Abstract Data Types

Abstract Data Type (ADT): A description of *information* and a collection of *operations* on that information.

The information is accessed *only* through the operations.

We can have various realizations of an ADT, which specify:

- How the information is stored (data structure)
- How the operations are performed (algorithms)

Stack ADT

Stack: an ADT consisting of a collection of items with operations:

- push: inserting an item
- pop: removing (and typically returning) the most recently inserted item

Items are removed in LIFO (last-in first-out) order.

Items enter the stack at the *top* and are removed from the *top*.

We can have extra operations: size, isEmpty, and top

Applications: Addresses of recently visited web sites, procedure calls

Realizations of Stack ADT

- using arrays
- using linked lists

Queue ADT

Queue: an ADT consisting of a collection of items with operations:

- enqueue: inserting an item
- dequeue: removing (and typically returning) the least recently inserted item

Items are removed in FIFO (first-in first-out) order.

Items enter the queue at the *rear* and are removed from the *front*.

We can have extra operations: size, isEmpty, and front

Applications: Waiting lines, printer queues

Realizations of Queue ADT

- using (circular) arrays
- using linked lists

Priority Queue ADT

Priority Queue: An ADT consisting of a collection of items (each having a **priority**) with operations

- insert: inserting an item tagged with a priority
- deleteMax: removing and returning the item of highest priority

deleteMax is also called extractMax or getmax.

The priority is also called key.

The above definition is for a **maximum-oriented** priority queue. A **minimum-oriented** priority queue is defined in the natural way, replacing operation deleteMax by deleteMin,

Applications: typical "todo" list, simulation systems, sorting

Using a Priority Queue to Sort

```
PQ-Sort(A[0..n-1])
      initialize PQ to an empty priority queue
   for i \leftarrow 0 to n-1 do
3.
           PQ.insert(A[i])
4. for i \leftarrow n-1 down to 0 do
           A[i] \leftarrow PQ.deleteMax()
5.
```

- Note: Run-time depends on how we implement the priority queue.
- Sometimes written as: $O(initialization + n \cdot insert + n \cdot deleteMax)$

Petrick (SCS, UW) CS240 - Module 2 Fall 2020 6 / 25

Realizations of Priority Queues

Realization 1: unsorted arrays

- *insert*: *O*(1)
- deleteMax: O(n)

Note: We assume **dynamic arrays**, i. e., expand by doubling as needed. (Amortized over all insertions this takes O(1) extra time.)

Using unsorted linked lists is identical.

PQ-sort with this realization yields selection sort.

Realization 2: sorted arrays

- insert: O(n)
- deleteMax: O(1)

Using sorted linked lists is identical.

PQ-sort with this realization yields insertion sort.

Realization 3: Heaps

A (binary) heap is a certain type of binary tree.

You should know:

- A binary tree is either
 - ► empty, or
 - consists of three parts: a node and two binary trees (left subtree and right subtree).
- Terminology: root, leaf, parent, child, level, sibling, ancestor, descendant, etc.
- Any binary tree with n nodes has height at least $\log(n+1)-1\in\Omega(\log n)$.

Example Heap

In our examples we only show the priorities, and we show them directly in the node. A more accurate picture would be (priority = 50, <other info>)

Heaps - Definition

A **heap** is a binary tree with the following two properties:

- Structural Property: All the levels of a heap are completely filled, except (possibly) for the last level. The filled items in the last level are left-justified.
- Weap-order Property: For any node i, the key of the parent of i is larger than or equal to key of i.

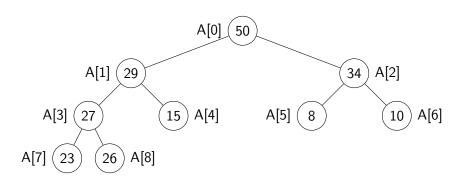

The full name for this is max-oriented binary heap.

Lemma: The height of a heap with n nodes is $\Theta(\log n)$.

Storing Heaps in Arrays

Heaps should not be stored as binary trees!

Let H be a heap of n items and let A be an array of size n. Store root in A[0] and continue with elements *level-by-level* from top to bottom, in each level left-to-right.

Heaps in Arrays - Navigation

It is easy to navigate the heap using this array representation:

- the root node is at index 0
 (We use "node" and "index" interchangeably in this implementation.)
- the *left child* of node i (if it exists) is node 2i + 1
- the right child of node i (if it exists) is node 2i + 2
- the parent of node i (if it exists) is node $\lfloor \frac{i-1}{2} \rfloor$
- the *last* node is n-1

We should hide implementation details using helper-functions!

functions root(), parent(i), last(n), etc.

 - Towards the Selection Problem

Insert in Heaps

- Place the new key at the first free leaf
- The heap-order property might be violated: perform a fix-up:

```
fix-up(A, i)

i: an index corresponding to a node of the heap

1. while parent(i) exists and A[parent(i)].key < A[i].key do

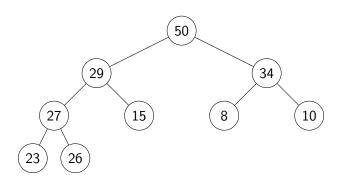

2. swap A[i] and A[parent(i)]

3. i \leftarrow parent(i)
```

The new item "bubbles up" until it reaches its correct place in the heap.

Time: $O(\text{height of heap}) = O(\log n)$.

fix-up example

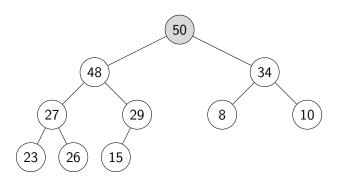

deleteMax in Heaps

- The maximum item of a heap is just the root node.
- We replace root by the last leaf (last leaf is taken out).
- The heap-order property might be violated: perform a fix-down:

```
fix-down(A, n, i)
A: an array that stores a heap of size n
i: an index corresponding to a node of the heap
       while i is not a leaf do
1.
            // Find the child with the larger key
3.
            i \leftarrow \text{left child of } i
            if (j is not last(n) and A[j+1].key > A[j].key)
4.
5.
                 i \leftarrow j + 1
6. if A[i].key \ge A[j].key break
            swap A[i] and A[i]
7.
            i \leftarrow i
8.
```

Time: $O(\text{height of heap}) = O(\log n)$.

deleteMax example

Priority Queue Realization Using Heaps

• Store items in array A and globally keep track of size

```
insert(x)

1. increase size

2. \ell \leftarrow last(size)

3. A[\ell] \leftarrow x

4. fix-up(A, \ell)
```

```
deleteMax()

1. \ell \leftarrow last(size)

2. swap \ A[root()] \ and \ A[\ell]

3. decrease size

4. fix-down(A, size, root())

5. \mathbf{return} \ A[\ell]
```

insert and deleteMax: $O(\log n)$

Sorting using heaps

Recall: Any priority queue can be used to sort in time

$$O(initialization + n \cdot insert + n \cdot deleteMax)$$

Using the binary-heaps implementation of PQs, we obtain:

```
PQsortWithHeaps(A)

1. initialize H to an empty heap

2. for i \leftarrow 0 to n-1 do

3. H.insert(A[i])

4. for i \leftarrow n-1 down to 0 do

5. A[i] \leftarrow H.deleteMax()
```

- both operations run in $O(\log n)$ time for heaps
- \rightsquigarrow PQ-Sort using heaps takes $O(n \log n)$ time.
 - Can improve this with two simple tricks → Heapsort
 - 1 Heaps can be built faster if we know all input in advance.
 - 2 Can use the same array for input and heap. $\rightsquigarrow O(1)$ auxiliary space!

Building Heaps with Fix-up

Problem: Given n items all at once (in $A[0 \cdots n-1]$) build a heap containing all of them.

Solution 1: Start with an empty heap and insert items one at a time:

simpleHeapBuilding(A)

A: an array

- 1. initialize H as an empty heap
- 2. **for** $i \leftarrow 0$ **to** size(A) 1 **do**
- H.insert(A[i])

This corresponds to doing *fix-ups* Worst-case running time: $\Theta(n \log n)$.

Building Heaps with Fix-down

Problem: Given n items all at once (in $A[0 \cdots n-1]$) build a heap containing all of them.

Solution 2: Using *fix-downs* instead:

```
heapify(A)

A: an array

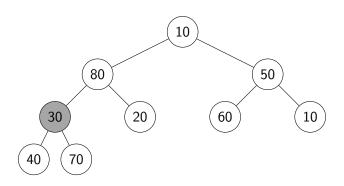

1. n \leftarrow A.size()

2. for i \leftarrow parent(last(n)) downto 0 do

3. fix-down(A, n, i)
```

A careful analysis yields a worst-case complexity of $\Theta(n)$. A heap can be built in linear time.

heapify example

HeapSort

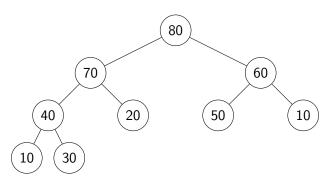

- Idea: PQ-sort with heaps.
- \circ O(1) auxiliary space: Use same input-array A for storing heap.

```
HeapSort(A, n)
1. // heapify
2. n \leftarrow A.size()
3. for i \leftarrow parent(last(n)) downto 0 do
           fix-down(A, n, i)
4.
   // repeatedly find maximum
   while n > 1
           // delete the maximum
           swap items at A[root()] and A[last(n)]
8.
9.
           decrease n
       fix-down(A, n, root())
10.
```

The for-loop takes $\Theta(n)$ time and the while-loop takes $O(n \log n)$ time.

Heapsort example

Continue with the example from heapify:

Heap summary

- Binary heap: A binary tree that satisfies structural property and heap-order property.
- Heaps are one possible realization of ADT PriorityQueue:
 - ► insert takes time $O(\log n)$
 - ▶ deleteMax takes time O(log n)
 - ▶ Also supports findMax in time O(1)
- A binary heap can be built in linear time.
- PQ-sort with binary heaps leads to a sorting algorithm with $O(n \log n)$ worst-case run-time (\rightsquigarrow HeapSort)
- We have seen here the *max-oriented version* of heaps (the maximum priority is at the root).
- There exists a symmetric min-oriented version that supports insert and deleteMin with the same run-times.

Finding the largest items

Problem: Find the *kth largest item* in an array A of n distinct numbers.

Solution 1: Make *k* passes through the array, deleting the maximum number each time.

Complexity: $\Theta(kn)$.

Solution 2: Sort *A*, then return A[n-k].

Complexity: $\Theta(n \log n)$.

Solution 3: Scan the array and maintain the k largest numbers seen so

far in a min-heap

Complexity: $\Theta(n \log k)$.

Solution 4: Create a max-heap with heapify(A). Call deleteMax(A) k

times.

Complexity: $\Theta(n + k \log n)$.
