Data Storage and Transmission

The problem: How to store and transmit data?

Source text The original data, string S of characters from the
source alphabet Σ_S

Coded text The encoded data, string C of characters from the
coded alphabet Σ_C

Encoding An algorithm mapping source texts to coded texts

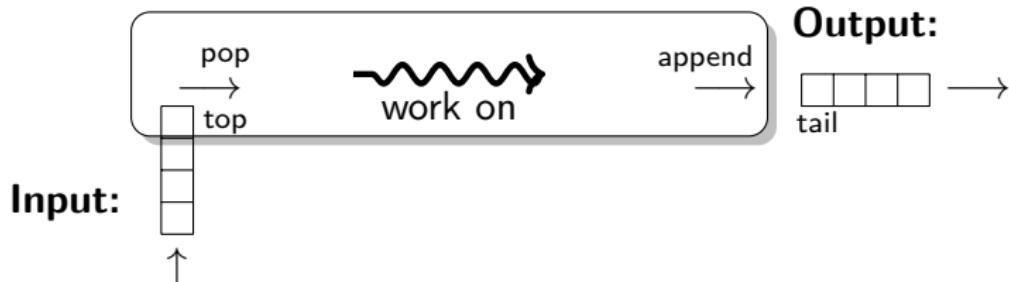

Decoding An algorithm mapping coded texts
back to their original source text

Note: Source “text” can be any sort of data (not always text!)

Usually the coded alphabet Σ_C is just binary: $\{0, 1\}$.

Detour: streams

Usually S and C are stored as streams.

- Input-stream: Read one character at a time (via *top/pop*)
Also supports *isEmpty*. Sometimes need *reset*.
- Output-stream: Write one character at a time (via *append*)
- Convenient for handling huge texts (start processing while loading)

Judging Encoding Schemes

We can always measure efficiency of encoding/decoding algorithms.

What other goals might there be?

Judging Encoding Schemes

We can always measure efficiency of encoding/decoding algorithms.

What other goals might there be?

- Processing speed
- Reliability (e.g. error-correcting codes)
- Security (e.g. encryption)
- Size

Judging Encoding Schemes

We can always measure efficiency of encoding/decoding algorithms.

What other goals might there be?

- Processing speed
- Reliability (e.g. error-correcting codes)
- Security (e.g. encryption)
- Size (*main objective here*)

Encoding schemes that try to minimize the size of the coded text perform **data compression**. We will measure the **compression ratio**:

$$\frac{|C| \cdot \lceil \log |\Sigma_C| \rceil}{|S| \cdot \lceil \log |\Sigma_S| \rceil}$$

Types of Data Compression

Logical vs. Physical

- **Logical Compression** uses the meaning of the data and only applies to a certain domain (e.g. sound recordings)
- **Physical Compression** only knows the physical bits in the data, not the meaning behind them

Lossy vs. Lossless

- **Lossy Compression** achieves better compression ratios, but the decoding is approximate; the exact source text S is not recoverable
- **Lossless Compression** always decodes S exactly

For media files, lossy, logical compression is useful (e.g. JPEG, MPEG)

We will concentrate on *physical, lossless* compression algorithms.

These techniques can safely be used for any application.

Character Encodings

A **character encoding** (or more precisely **character-by-character encoding**) maps each character in the source alphabet to a string in coded alphabet.

$$E : \Sigma_S \rightarrow \Sigma_C^*$$

For $c \in \Sigma_S$, we call $E(c)$ the **codeword** of c

Two possibilities:

- **Fixed-length code:** All codewords have the same length.
- **Variable-length code:** Codewords may have different lengths.

Fixed-length codes

ASCII (American Standard Code for Information Interchange), 1963:

char	null	start of heading	start of text	end of text	...	0	1	...	A	B	...	~	delete
code	0	1	2	3	...	48	49	...	65	66	...	126	127

- 7 bits to encode 128 possible characters:
“control codes”, spaces, letters, digits, punctuation

$$A \cdot P \cdot P \cdot L \cdot E \rightarrow (65, 80, 80, 76, 69) \rightarrow 1000001\ 1010000\ 1010000\ 1001100\ 1000101$$

- Standard in *all* computers and often our source alphabet.
- Not well-suited for non-English text:
ISO-8859 extends to 8 bits, handles most Western languages

Other (earlier) examples: Caesar shift, Baudot code, Murray code

To decode a fixed-length code (say codewords have k bits), we look up each k -bit pattern in a table.

Variable-Length Codes

Overall goal: Find an encoding that is short.

Observation: Some letters in Σ occur more often than others.
So let's use shorter codes for more frequent characters.

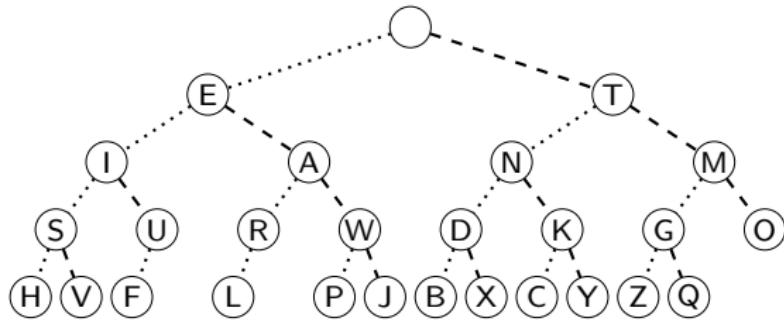

For example, the frequency of letters in typical English text is:

e	12.70%	d	4.25%	p	1.93%
t	9.06%	l	4.03%	b	1.49%
a	8.17%	c	2.78%	v	0.98%
o	7.51%	u	2.76%	k	0.77%
i	6.97%	m	2.41%	j	0.15%
n	6.75%	w	2.36%	x	0.15%
s	6.33%	f	2.23%	q	0.10%
h	6.09%	g	2.02%	z	0.07%
r	5.99%	y	1.97%		

Variable-Length Codes

Example 1: Morse code.

A	• -	N	- •
B	- - - .	O	- - - -
C	- - - . -	P	• - - - •
D	- - . -	Q	- - - . - -
E	.	R	• - - -
F	• - - - .	S	• • •
G	- - - .	T	-
H	• • • •	U	• • -
I	• •	V	• • - -
J	- - - -	W	- - -
K	- - . -	X	- - - - .
L	- - - . -	Y	- - - - -
M	- -	Z	- - - . -

Example 2: UTF-8 encoding of Unicode:

- Encodes any Unicode character (more than 107,000 characters) using 1-4 bytes

Encoding

Assume we have some character encoding $E : \Sigma_S \rightarrow \Sigma_C^*$.

- Note that E is a dictionary with keys in Σ_S .
- E.g. could store E as array indexed by Σ_S .

charByChar::encoding(E, S, C)

E : the encoding dictionary

S : input-stream with characters in Σ_S , C : output-stream

1. **while** S is non-empty
2. $x \leftarrow E.\text{search}(S.\text{pop}())$
3. $C.\text{append}(x)$

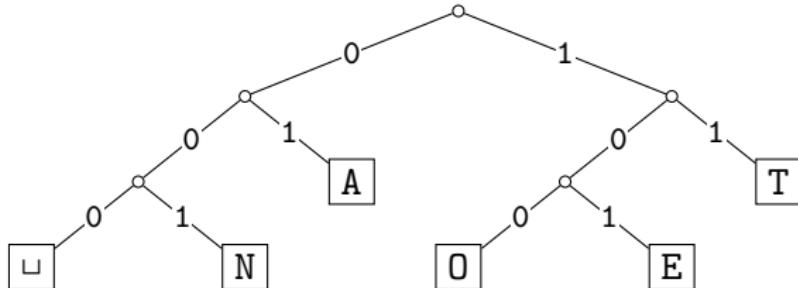

Example: encode text “WATT” with Morse code:

Decoding

The **decoding algorithm** must map Σ_C^* to Σ_S^* .

- The code must be *uniquely decodable*.
 - ▶ This is false for Morse code as described!
 - — — • — — — decodes to WATT and ANO and WJ.
(Morse code uses ‘end of character’ pause to avoid ambiguity.)
- From now on only consider **prefix-free** codes E :
no codeword is a prefix of another
- This corresponds to a *trie* with characters of Σ_S only at the leaves.

- The codewords need no end-of-string symbol $\$$ if E is prefix-free.

Decoding of Prefix-Free Codes

Any prefix-free code is uniquely decodable (why?)

prefixFree::decoding(T , C , S)

T : trie of a prefix-free code

C : input-stream with characters in Σ_C , S : output-stream

1. **while** C is non-empty
2. $r \leftarrow T.root$
3. **while** r is not a leaf
4. **if** C is empty or r has no child labelled $C.top()$
5. **return** “invalid encoding”
6. $r \leftarrow$ child of r that is labelled with $C.pop()$
7. $S.append$ (character stored at r)

Run-time: $O(|C|)$.

Encoding from the Trie

We can also encode directly from the trie.

prefixFree::encoding(T, S, C)

T : trie of a prefix-free code

S : input-stream with characters in Σ_S , C : output-stream

1. $E \leftarrow$ array of nodes in T indexed by Σ_S
2. **for** all leaves ℓ in T
3. $E[\text{character at } \ell] \leftarrow \ell$
4. **while** S is non-empty
5. $w \leftarrow$ empty string
6. $v \leftarrow E[S.\text{pop}()]$
7. **while** v is not the root
8. $w.\text{prepend}(\text{character from } v \text{ to its parent})$
9. // Now w is the encoding of character from S .
10. $C.append(w)$

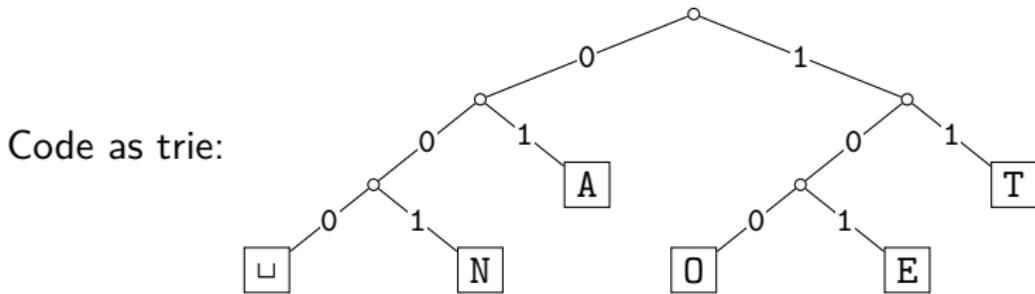

Run-time: $O(|T| + |C|)$

This is in $O(|\Sigma_S| + |C|)$ if T has no node with 1 child.

Example: Prefix-free Encoding/Decoding

Code as table:

$c \in \Sigma_S$	\sqcup	A	E	N	O	T
$E(c)$	000	01	101	001	100	11

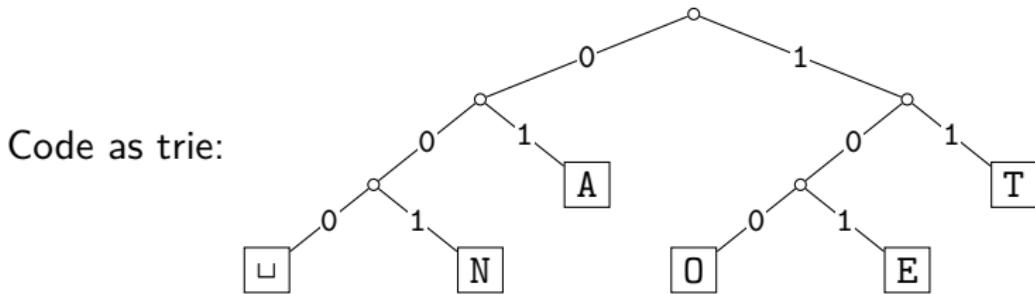

- Encode AN_◻ANT
- Decode 111000001010111

Example: Prefix-free Encoding/Decoding

Code as table:

$c \in \Sigma_S$	\sqcup	A	E	N	O	T
$E(c)$	000	01	101	001	100	11

- Encode AN_◻ANT → 010010000100111
- Decode 111000001010111 → T_◻EAT

- Burrows-Wheeler Transform

Huffman's Algorithm: Building the best trie

For a given source text S , how to determine the “best” trie that minimizes the length of C ?

- ① Determine frequency of each character $c \in \Sigma$ in S
- ② For each $c \in \Sigma$, create “ \boxed{c} ” (height-0 trie holding c).
- ③ Our tries have a *weight*: sum of frequencies of all letters in trie.
Initially, these are just the character frequencies.
- ④ Find the two tries with the minimum weight.
- ⑤ Merge these tries with new interior node; new weight is the sum.
(Corresponds to adding one bit to the encoding of each character.)
- ⑥ Repeat last two steps until there is only one trie left

What data structure should we store the tries in to make this efficient?

Huffman's Algorithm: Building the best trie

For a given source text S , how to determine the “best” trie that minimizes the length of C ?

- ① Determine frequency of each character $c \in \Sigma$ in S
- ② For each $c \in \Sigma$, create “ \boxed{c} ” (height-0 trie holding c).
- ③ Our tries have a *weight*: sum of frequencies of all letters in trie.
Initially, these are just the character frequencies.
- ④ Find the two tries with the minimum weight.
- ⑤ Merge these tries with new interior node; new weight is the sum.
(Corresponds to adding one bit to the encoding of each character.)
- ⑥ Repeat last two steps until there is only one trie left

What data structure should we store the tries in to make this efficient?
A min-ordered heap! Step 4 is two *delete-mins*, Step 5 is *insert*

Example: Huffman tree construction

Example text: GREENENERGY, $\Sigma_S = \{G, R, E, N, Y\}$

Character frequencies: G : 2, R : 2, E : 4, N : 2, Y : 1

2

G

Character frequencies: G : 2, R : 2, E : 4, N : 2, Y : 1

Example: Huffman tree construction

Example text: GREENENERGY, $\Sigma_S = \{G, R, E, N, Y\}$

Character frequencies: G : 2, R : 2, E : 4, N : 2, Y : 1

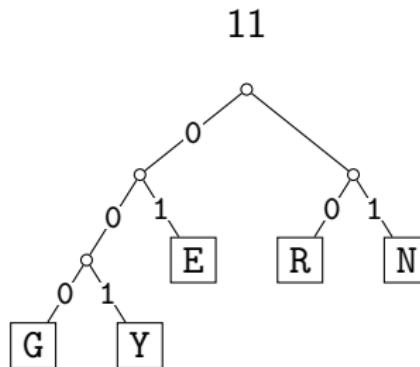

GREENENERGY →

Example: Huffman tree construction

Example text: GREENENERGY, $\Sigma_S = \{G, R, E, N, Y\}$

Character frequencies: G : 2, R : 2, E : 4, N : 2, Y : 1

GREENENERGY → 000 10 01 01 11 01 11 01 10 000 001

Compression ratio: $\frac{25}{11 \cdot \lceil \log 5 \rceil} \approx 76\%$

(If the Huffman tree is full, for example, if the frequencies were equal or almost equal, the frequencies are not skewed enough to lead to good compression. In this case, compression ratio = 1.)

Huffman's Algorithm: Pseudocode

Huffman::encoding(S, C)

S: input-stream with characters in Σ_S , C: output-stream

1. $f \leftarrow$ array indexed by Σ_S , initially all-0 // frequencies
2. **while** S is non-empty **do** increase $f[S.pop()]$ by 1
3. $Q \leftarrow$ min-oriented priority queue that stores tries // initialize PQ
4. **for** all $c \in \Sigma_S$ with $f[c] > 0$ **do**
 - 5. $Q.insert(\text{single-node trie for } c \text{ with weight } f[c])$
6. **while** $Q.size > 1$ **do** // build decoding trie
 - 7. $T_1 \leftarrow Q.deleteMin()$, $f_1 \leftarrow$ weight of T_1
 - 8. $T_2 \leftarrow Q.deleteMin()$, $f_2 \leftarrow$ weight of T_2
 - 9. $Q.insert(\text{trie with } T_1, T_2 \text{ as subtrees and weight } f_1 + f_2)$
 - 10. $T \leftarrow Q.deleteMin$
11. $C.append(\text{encoding trie } T)$
12. Re-set input-stream S
13. *prefixFree::encoding(T, S, C)* // actual encoding

Huffman Coding Discussion

- We require $|\Sigma_S| \geq 2$.
- Note: constructed trie is *not unique*.
So decoding trie must be transmitted along with the coded text.
- This may make encoding bigger than source text!
- Encoding must pass through text twice (to compute frequencies and to encode). Cannot use a stream unless it can be re-set.
- Encoding run-time: $O(|\Sigma_S| \log |\Sigma_S| + |C|)$
- Decoding run-time: $O(|C|)$
- The constructed trie is *optimal* in the sense that coded text is shortest (among all prefix-free character-encodings with $\Sigma_C = \{0, 1\}$).
See course notes for proof.
- Many variations (give tie-breaking rules, estimate frequencies, adaptively change encoding,)

Outline

- 1 Compression
 - Encoding Basics
 - Huffman Codes
 - Run-Length Encoding
 - Lempel-Ziv-Welch
 - bzip2
 - Burrows-Wheeler Transform

Run-Length Encoding

- Variable-length code
- Example of **multi-character encoding**: multiple source-text characters receive one code-word.
- The source alphabet and coded alphabet are both binary: {0, 1}.
- Decoding dictionary is uniquely defined and not explicitly stored.

When to use: if S has long runs: 00000 111 0000

Encoding idea:

- Give the first bit of S (either 0 or 1)
- Then give a sequence of integers indicating run lengths.
- We don't have to give the bit for runs since they alternate.

Example becomes: 0, 5, 3, 4

Question: How to encode a run length k in binary?

Prefix-free Encoding for Positive Integers

Use **Elias gamma coding** to encode k :

- $\lfloor \log k \rfloor$ copies of 0, followed by
- binary representation of k (always starts with 1)

k	$\lfloor \log k \rfloor$	k in binary	encoding
1	0	1	1
2	1	10	010
3	1	11	011
4	2	100	00100
5	2	101	00101
6	2	110	00110
\vdots	\vdots	\vdots	\vdots

RLE Encoding

RLE::encoding(*S*, *C*)

S : input-stream of bits, C : output-stream

- ```

1. $b \leftarrow S.\text{top}(); C.\text{append}(b)$
2. while S is non-empty do
3. $k \leftarrow 1$ // length of run
4. while (S is non-empty and $S.\text{top}() = b$) do
5. $k++; S.\text{pop}()$
6. // compute and append Elias gamma code
7. $K \leftarrow$ empty string
8. while $k > 1$
9. $C.\text{append}(0)$
10. $K.\text{prepend}(k \bmod 2)$
11. $k \leftarrow \lfloor k/2 \rfloor$
12. $K.\text{prepend}(1)$ // K is binary encoding of k
13. $C.\text{append}(K)$
14. $b \leftarrow 1 - b$

```

# RLE Decoding

*RLE::decoding*( $C, S$ )

$C$ : input-stream of bits ,  $S$ : output-stream

1.  $b \leftarrow C.pop()$  // bit-value for the current run
2. **while**  $C$  is non-empty
3.      $\ell \leftarrow 0$  // length of base-2 number -1
4.     **while**  $C.pop() = 0$  **do**  $\ell++$
5.      $k \leftarrow 1$  // base-2 number converted
6.     **for** ( $j \leftarrow 1$  to  $\ell$ ) **do**  $k \leftarrow k * 2 + C.pop()$
7.     **for** ( $j \leftarrow 1$  to  $k$ ) **do**  $S.append(b)$
8.      $b \leftarrow 1 - b$

If  $C.pop()$  is called when there are no bits left, then  $C$  was not valid input.

## RLE Example

Encoding:

$S = \textcolor{red}{1}11111100100000000000000000001111111111$

$C = \textcolor{red}{1}$

Decoding:

$C = 00001101001001010$

$S =$

## RLE Example

## Encoding:

k = 7

$$C = 100111$$

## Decoding:

$$C = 00001101001001010$$

$S =$

## RLE Example

## Encoding:

$$k = 2$$

$$C = 100111\textcolor{red}{0}10$$

## Decoding:

$$C = 00001101001001010$$

$S =$

## RLE Example

## Encoding:

k = 1

$$C = 100111010\textcolor{red}{1}$$

## Decoding:

$$C = 00001101001001010$$

$S =$

## RLE Example

## Encoding:

$$S = 1111111001\textcolor{red}{00000000000000000000}1111111111$$

$$k = 20$$

$$C = 1001110101\textcolor{red}{000010100}$$

Decoding:

$$C = 00001101001001010$$

$S =$

## RLE Example

## Encoding:

$$k = 11$$

$$C = 1001110101000010100\textcolor{red}{0001011}$$

## Decoding:

$$C = 00001101001001010$$

$S =$

## RLE Example

## Encoding:

$$S = 111111100100000000000000000000001111111111$$

$$C = 10011101010000101000001011$$

Compression ratio: 26/41 ≈ 63%

## Decoding:

$$C = 00001101001001010$$

$S =$

## RLE Example

Encoding:

$S = 11111110010000000000000000001111111111$

$C = 10011101010000101000001011$

Compression ratio:  $26/41 \approx 63\%$

Decoding:

$C = 00001101001001010$

$S =$

## RLE Example

Encoding:

$S = 11111110010000000000000000001111111111$

$C = 10011101010000101000001011$

Compression ratio:  $26/41 \approx 63\%$

Decoding:

$C = 00001101001001010$

$b = 0$

$S =$

## RLE Example

Encoding:

$S = 11111110010000000000000000001111111111$

$C = 10011101010000101000001011$

Compression ratio:  $26/41 \approx 63\%$

Decoding:

$$S = 11111110010000000000000000000000111111111$$

$$C = 10011101010000101000001011$$

Compression ratio: 26/41 ≈ 63%

## Decoding:

$$C = 000011010010010\textcolor{red}{10}$$

$$b = 1$$

$$\ell = 1$$

$$k = 2$$

$$S \equiv 000000000000011110\textcolor{red}{11}$$

# RLE Properties

- An all-0 string of length  $n$  would be compressed to  $2\lfloor \log n \rfloor + 2 \in o(n)$  bits.
- Usually, we are not that lucky:
  - ▶ No compression until run-length  $k \geq 6$
  - ▶ *Expansion* when run-length  $k = 2$  or  $4$
- Used in some image formats (e.g. TIFF)
- Method can be adapted to larger alphabet sizes (but then the encoding of each run must also store the character)
- Method can be adapted to encode *only* runs of 0 (we will need this soon)

# Outline

## 1 Compression

- Encoding Basics
- Huffman Codes
- Run-Length Encoding
- **Lempel-Ziv-Welch**
- bzip2
- Burrows-Wheeler Transform

# Longer Patterns in Input

Huffman and RLE take advantage of frequent/repeated *single characters*.

**Observation:** Certain *substrings* are much more frequent than others.

- English text:
  - Most frequent digraphs: TH, ER, ON, AN, RE, HE, IN, ED, ND, HA
  - Most frequent trigraphs: THE, AND, THA, ENT, ION, TIO, FOR, NDE
- HTML: “<a href”, “<img src”, “<br>”
- Video: repeated background between frames, shifted sub-image

**Ingredient 1** for Lempel-Ziv-Welch compression: take advantage of such substrings *without* needing to know beforehand what they are.

# Adaptive Dictionaries

ASCII, UTF-8, and RLE use *fixed* dictionaries.

In Huffman, the dictionary is not fixed, but it is *static*: the dictionary is the same for the entire encoding/decoding.

**Ingredient 2** for LZW: *adaptive encoding*:

- There is a fixed initial dictionary  $D_0$ . (Usually ASCII.)
- For  $i \geq 0$ ,  $D_i$  is used to determine the  $i$ th output character
- After writing the  $i$ th character to output, both encoder and decoder update  $D_i$  to  $D_{i+1}$

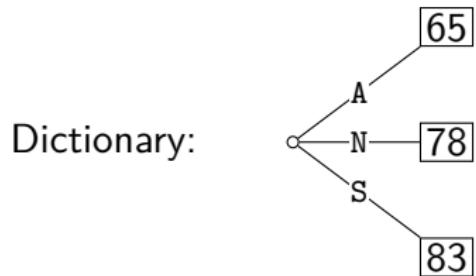

Encoder and decoder must both know how the dictionary changes.

## LZW Overview

- Start with dictionary  $D_0$  for  $|\Sigma_S|$ .  
Usually  $\Sigma_S = \text{ASCII}$ , then this uses codenumbers  $0, \dots, 127$ .
- Every step adds to dictionary a multi-character string, using codenumbers  $128, 129, \dots$ .
- Encoding:
  - ▶ Store current dictionary  $D_i$  as a trie.
  - ▶ Parse trie to find longest prefix  $w$  already in  $D_i$ .  
So all of  $w$  can be encoded with one number.
  - ▶ Add to dictionary the *substring that would have been useful*: add  $wK$  where  $K$  is the character that follows  $w$  in  $S$ .
  - ▶ This creates one child in trie at the leaf where we stopped.
- Output is a list of numbers. This is usually converted to bit-string with fixed-width encoding using 12 bits.
  - ▶ This limits the codenumbers to 4096.

## LZW Example

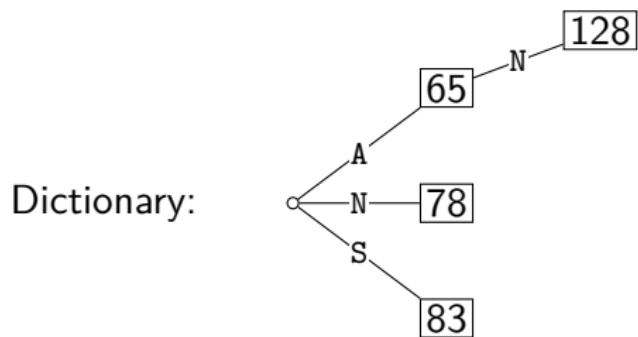

Text: A N A N A S A N N A

## LZW Example

Text: A N A N A S A N N A

65 78 128 65 83 128 129

Final output:   
65 78 128 65 83 128 129

## LZW encoding pseudocode

*LZW::encoding*( $S, C$ )

$S$  : input-stream of characters,  $C$ : output-stream

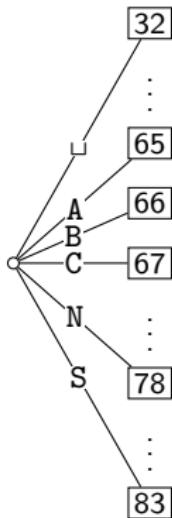

1. Initialize dictionary  $D$  with ASCII in a trie
2.  $idx \leftarrow 128$
3. **while**  $S$  is non-empty **do**
4.      $v \leftarrow$  root of trie  $D$
5.     **while** ( $S$  is non-empty and  $v$  has a child  $c$  labelled  $S.top()$ )
6.          $v \leftarrow c; S.pop()$
7.          $C.append$ (codenumber stored at  $v$ )
8.     **if**  $S$  is non-empty
9.         create child of  $v$  labelled  $S.top()$  with codenumber  $idx$
10.         $idx++$

# LZW decoding

- Build dictionary while reading string by imitating encoder.
- We are one step behind.
- Example:

| ASCII |   |
|-------|---|
| ...   |   |
| 32    | □ |
| ...   |   |
| ...   |   |
| 65    | A |
| 66    | B |
| 67    | C |
| ...   |   |
| 78    | N |
| ...   |   |
| 83    | S |
| ...   |   |

What encoder did:

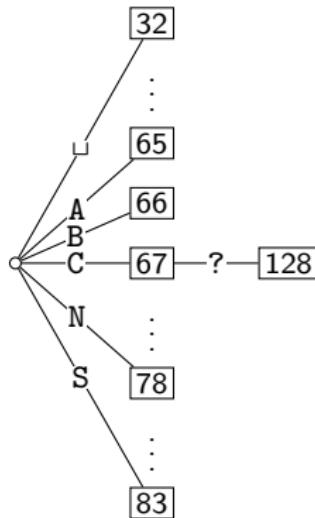

# LZW decoding

- Build dictionary while reading string by imitating encoder.
- We are one step behind.
- Example:

67  
C

| ASCII |   |
|-------|---|
| ...   |   |
| 32    | □ |
| ...   |   |
| ...   |   |
| 65    | A |
| 66    | B |
| 67    | C |
| ...   |   |
| 78    | N |
| ...   |   |
| 83    | S |
| ...   |   |

What encoder did:

## LZW decoding

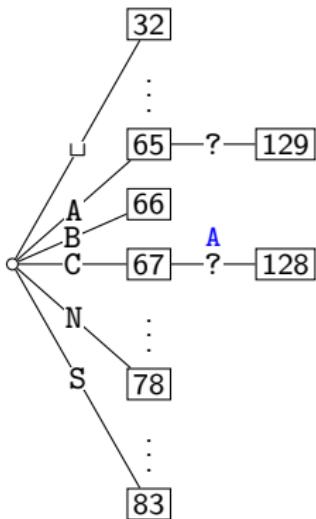

- Build dictionary while reading string by imitating encoder.
  - We are one step behind.

- Example:

| ASCII |   |
|-------|---|
| ...   |   |
| 32    | □ |
| ...   |   |
| ...   |   |
| 65    | A |
| 66    | B |
| 67    | C |
| ...   |   |
| 78    | N |
| ...   |   |
| 83    | S |
| ...   |   |

What encoder did:

Deduced one step later:

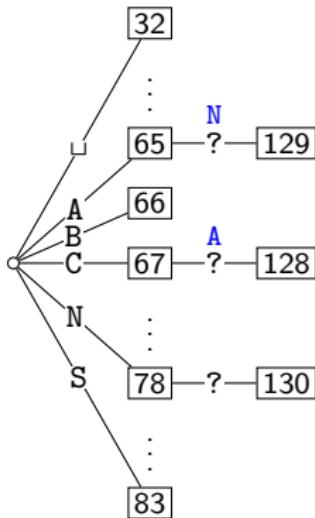

# LZW decoding

- Build dictionary while reading string by imitating encoder.
- We are one step behind.
- Example: 67 65 78  
C A N

| ASCII |   |
|-------|---|
| ...   |   |
| 32    | □ |
| ...   |   |
| ...   |   |
| 65    | A |
| 66    | B |
| 67    | C |
| ...   |   |
| 78    | N |
| ...   |   |
| 83    | S |
| ...   |   |

What encoder did:

Deduced one step later:

# LZW decoding

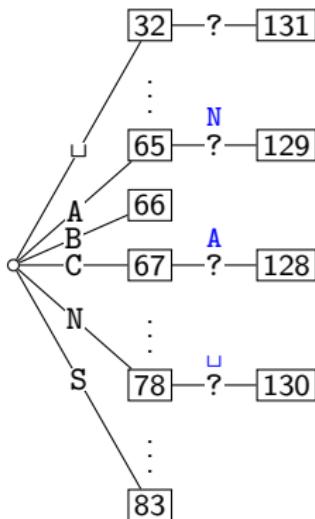

- Build dictionary while reading string by imitating encoder.
- We are one step behind.

- Example:  
    67   65   78   32  
    C       A       N       ◻

| ASCII |   |
|-------|---|
| ...   |   |
| 32    | ◻ |
| ...   |   |
| ...   |   |
| 65    | A |
| 66    | B |
| 67    | C |
| ...   |   |
| 78    | N |
| ...   |   |
| 83    | S |
| ...   |   |

What encoder did:

Deduced one step later:

# LZW decoding

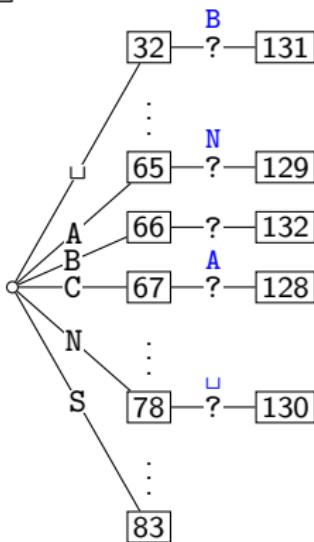

- Build dictionary while reading string by imitating encoder.
- We are one step behind.
- Example:

67 65 78 32 **66**  
C A N □ **B**

| ASCII |
|-------|
| ...   |
| 32 □  |
| ...   |
| ...   |
| 65 A  |
| 66 B  |
| 67 C  |
| ...   |
| 78 N  |
| ...   |
| 83 S  |
| ...   |

What encoder did:

Deduced one step later:

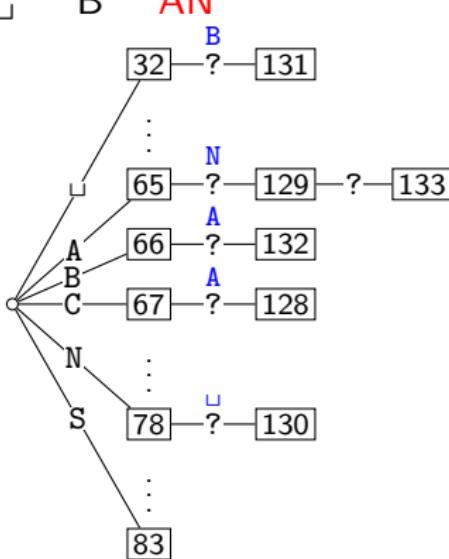

# LZW decoding

- Build dictionary while reading string by imitating encoder.
- We are one step behind.
- Example:  
    67   65   78   32   66   129  
    C      A      N      ◻      B      AN

| ASCII |   |
|-------|---|
| ...   |   |
| 32    | ◻ |
| ...   |   |
| 65    | A |
| 66    | B |
| 67    | C |
| ...   |   |
| 78    | N |
| ...   |   |
| 83    | S |
| ...   |   |

What encoder did:

Deduced one step later:

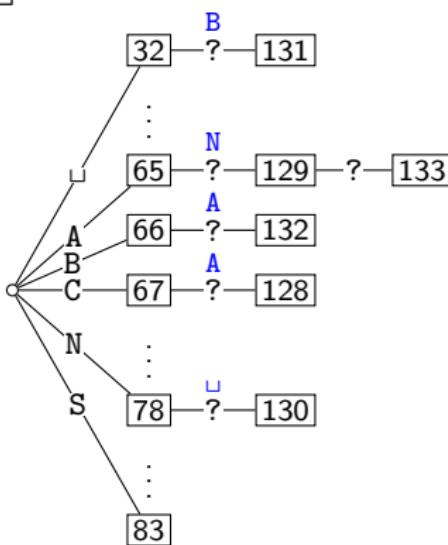

# LZW decoding

- Build dictionary while reading string by imitating encoder.
- We are one step behind.
- Example:  
    67   65   78   32   66   129   133  
    C      A      N      ◻      B      AN    ???

| ASCII |
|-------|
| ...   |
| 32 ◻  |
| ...   |
| ...   |
| 65 A  |
| 66 B  |
| 67 C  |
| ...   |
| 78 N  |
| ...   |
| 83 S  |
| ...   |

What encoder did:

Deduced one step later:

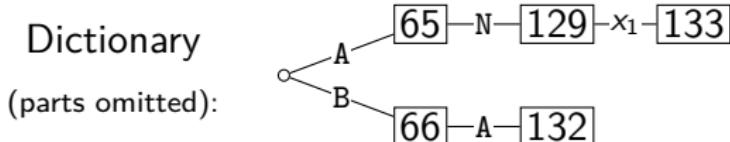

## LZW decoding: the catch

- In this example: Want to decode 133, but incomplete in dictionary!

## LZW decoding: the catch

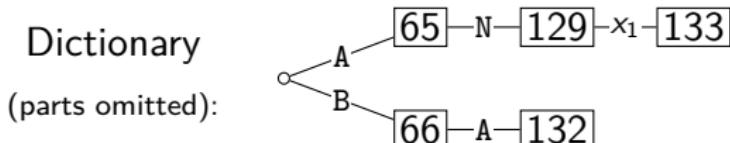

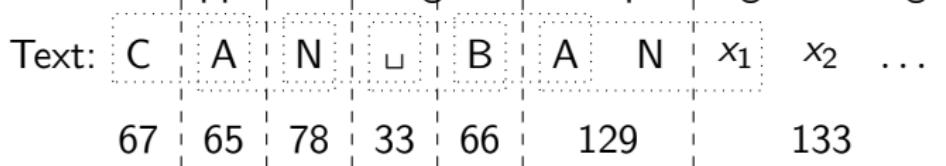

- In this example: Want to decode 133, but incomplete in dictionary!
- What happened during the corresponding encoding?

Text: C | A | N | u | B | A | N |  $x_1$  |  $x_2$  | ...  
67 | 65 | 78 | 33 | 66 | 129 |

## LZW decoding: the catch

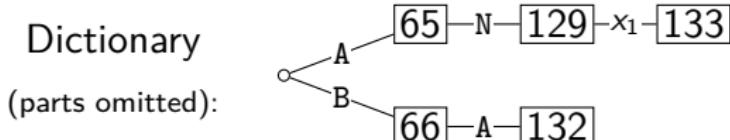

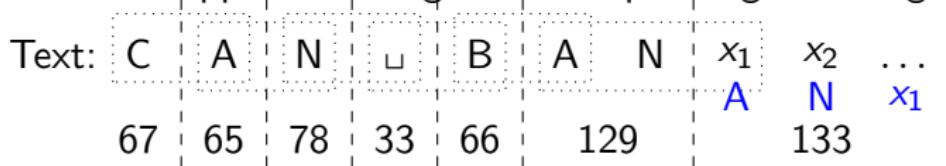

- In this example: Want to decode 133, but incomplete in dictionary!
- What happened during the corresponding encoding?

- We know: 133 encodes AN $x_1$  (for unknown  $x_1$ )

## LZW decoding: the catch

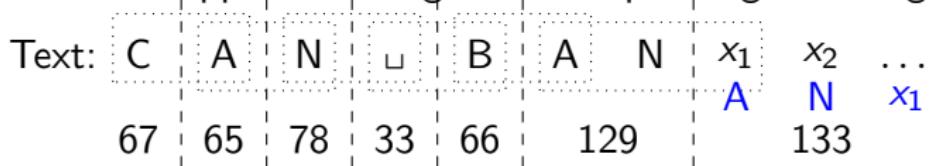

- In this example: Want to decode 133, but incomplete in dictionary!
- What happened during the corresponding encoding?

- We know: 133 encodes AN $x_1$  (for unknown  $x_1$ )
- We know: Next step uses 133 = AN $x_1$

## LZW decoding: the catch

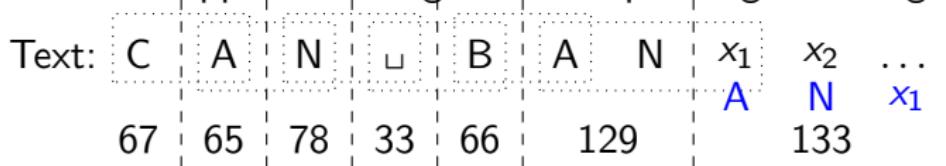

- In this example: Want to decode 133, but incomplete in dictionary!
- What happened during the corresponding encoding?

- We know: 133 encodes AN $x_1$  (for unknown  $x_1$ )
- We know: Next step uses  $133 = ANx_1$
- So  $x_1 = A$  and 133 encodes ANA

## LZW decoding: the catch

- In this example: Want to decode 133, but incomplete in dictionary!
- What happened during the corresponding encoding?

- We know: 133 encodes AN $x_1$  (for unknown  $x_1$ )
- We know: Next step uses 133 = AN $x_1$
- So  $x_1 = A$  and 133 encodes ANA

Generally: If code number is about to be added to  $D$ , then it encodes

“previous string + first character of previous string”

# LZW decoding pseudocode

*LZW::decoding(C, S)*

C: input-stream of integers, S: output-stream

1.  $D \leftarrow$  dictionary that maps  $\{0, \dots, 127\}$  to ASCII
2.  $idx \leftarrow 128$
3.  $code \leftarrow C.pop(); s \leftarrow D(code); S.append(s)$
4. **while** there are more codes in C **do**
5.  $s_{prev} \leftarrow s; code \leftarrow C.pop()$
6.     **if**  $code < idx$
7.          $s \leftarrow D(code)$
8.     **else if**  $code = idx$  // special situation!
9.          $s \leftarrow s_{prev} + s_{prev}[0]$
10.     **else** FAIL           // Encoding was invalid
11.      $S.append(s)$
12.      $D.insert(idx, s_{prev} + s[0])$
13.      $idx++$

| 98   b  | 114   | r          | 129    | ar             | 97, r             |
| ...     | 128   | ba         | 130    | rb             | 114, b            |
| 101   e | 114   | r          | 131    | bar            | 128, r            |
| ...     | 97    | a          | 132    | ra             | 114, a            |
| 110   n | 131   | bar        | 133    | ab             | 97, b             |
| ...     | 134   | barb       | 134    | barb           | 131, b            |
| 114   r | 129   | ar         | 135    | barba          | 134, a            |
| ...     | 101   | e          | 136    | are            | 129, e            |
|         |       |            | 137    |                |                   |

- To save space, store string as code of prefix + one character.
- Can still look up  $s$  in  $O(|s|)$  time.

## LZW decoding - second example

|    |    |     |     |     |    |     |      |     |     |     |
|----|----|-----|-----|-----|----|-----|------|-----|-----|-----|
| 98 | 97 | 114 | 128 | 114 | 97 | 131 | 134  | 129 | 101 | 110 |
| b  | a  | r   | ba  | r   | a  | bar | barb | ar  | e   | n   |

- No need to build a trie; store dictionary as array.

| ASCII   | input | decodes to | Code # | String (human) | String (computer) |
|---------|-------|------------|--------|----------------|-------------------|
| ...     | 98    | b          |        |                |                   |
| 97   a  | 97    | a          | 128    | ba             | 98, a             |
| 98   b  | 114   | r          | 129    | ar             | 97, r             |
| ...     | 128   | ba         | 130    | rb             | 114, b            |
| 101   e | 114   | r          | 131    | bar            | 128, r            |
| ...     | 97    | a          | 132    | ra             | 114, a            |
| 110   n | 131   | bar        | 133    | ab             | 97, b             |
| ...     | 134   | barb       | 134    | barb           | 131, b            |
| 114   r | 129   | ar         | 135    | barba          | 134, a            |
| ...     | 101   | e          | 136    | are            | 129, e            |
|         | 110   | n          | 137    | en             | 101, n            |

- To save space, store string as code of prefix + one character.
- Can still look up  $s$  in  $O(|s|)$  time.

## Lempel-Ziv-Welch discussion

- Encoding:  $O(|S|)$  time, uses a trie of encoded substrings to store the dictionary
- Decoding:  $O(|S|)$  time, uses an array indexed by code numbers to store the dictionary.
- Encoding and decoding need to go through the string only *once* and do not need to see the whole string  
⇒ can do compression while streaming the text
- Compresses quite well ( $\approx 45\%$  on English text).

### Brief history:

**LZ77** Original version (“sliding window”)

Derivatives: LZSS, LZFG, LZRW, LZP, DEFLATE, ...

DEFLATE used in (pk)zip, gzip, PNG

**LZ78** Second (slightly improved) version

Derivatives: LZW, LZMW, LZAP, LZY, ...

LZW used in compress, GIF (patent issues!)

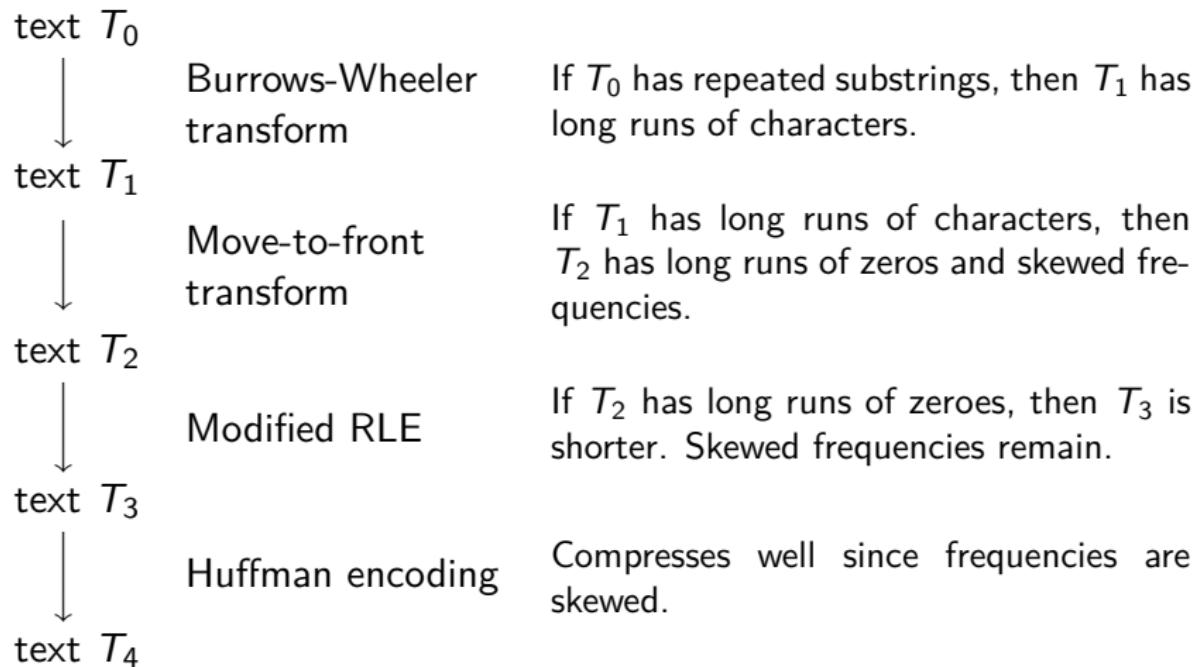

# Outline

## 1 Compression

- Encoding Basics
- Huffman Codes
- Run-Length Encoding
- Lempel-Ziv-Welch
- **bzip2**
- Burrows-Wheeler Transform

## bzip2 overview

To achieve even better compression, bzip2 uses *text transform*: Change input into a different text that is not necessarily shorter, but that has other desirable qualities.

## Move-to-Front transform

Recall the MTF heuristic for self-organizing search:

- Dictionary  $L$  is stored as an unsorted array or linked list
- After an element is accessed, move it to the front of the dictionary

How can we use this idea for transforming a text with repeat characters?

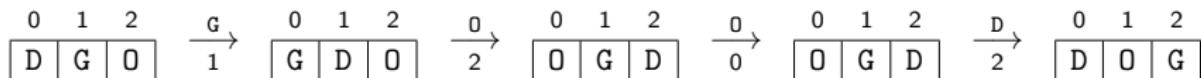

# Move-to-Front transform

Recall the MTF heuristic for self-organizing search:

- Dictionary  $L$  is stored as an unsorted array or linked list
- After an element is accessed, move it to the front of the dictionary

How can we use this idea for transforming a text with repeat characters?

- Encode each character of source text  $S$  by its index in  $L$ .
- After each encoding, update  $L$  with Move-To-Front heuristic.
- **Example:**  $S = \text{GOOD}$  becomes  $C = 1, 2, 0, 2$

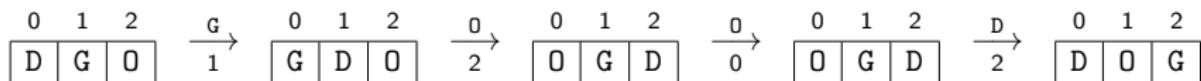

# Move-to-Front transform

Recall the MTF heuristic for self-organizing search:

- Dictionary  $L$  is stored as an unsorted array or linked list
- After an element is accessed, move it to the front of the dictionary

How can we use this idea for transforming a text with repeat characters?

- Encode each character of source text  $S$  by its index in  $L$ .
- After each encoding, update  $L$  with Move-To-Front heuristic.
- **Example:**  $S = \text{GOOD}$  becomes  $C = 1, 2, 0, 2$

**Observe:** A character in  $S$  repeats  $k$  times  $\Leftrightarrow C$  has run of  $k-1$  zeroes

**Observe:**  $C$  contains lots of small numbers and few big ones.

$C$  has the same length as  $S$ , but better properties.

# Move-to-Front Encoding/Decoding

## *MTF::encoding*( $S, C$ )

1.  $L \leftarrow$  array with  $\Sigma_S$  in some pre-agreed, fixed order (usually ASCII)
2. **while**  $S$  is not empty **do**
3.      $c \leftarrow S.pop()$
4.      $i \leftarrow$  index such that  $L[i] = c$
5.      $C.append(i)$
6.     **for**  $j = i - 1$  down to 0
7.         swap  $L[j]$  and  $L[j + 1]$

Decoding works in *exactly* the same way:

## *MTF::decoding*( $C, S$ )

1.  $L \leftarrow$  array with  $\Sigma_S$  in some pre-agreed, fixed order (usually ASCII)
2. **while**  $C$  is not empty **do**
3.      $i \leftarrow$  next integer from  $C$
4.      $S.append(L[i])$
5.     **for**  $j = i - 1$  down to 0
6.         swap  $L[j]$  and  $L[j + 1]$

# Outline

## 1 Compression

- Encoding Basics
- Huffman Codes
- Run-Length Encoding
- Lempel-Ziv-Welch
- bzip2
- Burrows-Wheeler Transform

# Burrows-Wheeler Transform

## Idea:

- **Permute** the source text  $S$ : the coded text  $C$  has the exact same letters (and the same length), but in a different order.
- **Goal:** If  $S$  has repeated substrings, then  $C$  should have long runs of characters.
- We need to choose the permutation carefully, so that we can **decode** correctly.

## Details:

- Assume that the source text  $S$  ends with end-of-word character  $\$$  that occurs nowhere else in  $S$ .
- A **cyclic shift** of  $S$  is the concatenation of  $S[i+1..n-1]$  and  $S[0..i]$ , for  $0 \leq i < n$ .
- The encoded text  $C$  consists of the last characters of the cyclic shifts of  $S$  after sorting them.

# BWT Encoding Example

$S = \text{alf} \sqcup \text{eats} \sqcup \text{alfalfa\$}$

① Write all cyclic shifts

alf  $\sqcup$  eats  $\sqcup$  alfalfa\$  
lf  $\sqcup$  eats  $\sqcup$  alfalfa\$a  
f  $\sqcup$  eats  $\sqcup$  alfalfa\$al  
 $\sqcup$  eats  $\sqcup$  alfalfa\$alf  
eats  $\sqcup$  alfalfa\$alf  $\sqcup$   
ats  $\sqcup$  alfalfa\$alf  $\sqcup$  e  
ts  $\sqcup$  alfalfa\$alf  $\sqcup$  ea  
s  $\sqcup$  alfalfa\$alf  $\sqcup$  eat  
 $\sqcup$  alfalfa\$alf  $\sqcup$  eats  
alfalfa\$alf  $\sqcup$  eats  $\sqcup$   
lfalfa\$alf  $\sqcup$  eats  $\sqcup$  a  
falfa\$alf  $\sqcup$  eats  $\sqcup$  al  
alfa\$alf  $\sqcup$  eats  $\sqcup$  alf  
lfa\$alf  $\sqcup$  eats  $\sqcup$  alfa  
fa\$alf  $\sqcup$  eats  $\sqcup$  alfa  
a\$alf  $\sqcup$  eats  $\sqcup$  alfalfa  
\$alf  $\sqcup$  eats  $\sqcup$  alfalfa

# BWT Encoding Example

$S = \text{alf} \sqcup \text{eats} \sqcup \text{alfalfa\$}$

- ① Write all cyclic shifts
- ② Sort cyclic shifts

\$alf  $\sqcup$  eats  $\sqcup$  alfalfa  
 $\sqcup$  alfalfa\$ alf  $\sqcup$  eats  
 $\sqcup$  eats  $\sqcup$  alfalfa\$ alf  
a\$ alf  $\sqcup$  eats  $\sqcup$  alfalfa

alfa\$ alf  $\sqcup$  eats  $\sqcup$  alf  
alfalfa\$ alf  $\sqcup$  eats  $\sqcup$   
ats  $\sqcup$  alfalfa\$ alf  $\sqcup$ e  
eats  $\sqcup$  alfalfa\$ alf  $\sqcup$   
f  $\sqcup$  eats  $\sqcup$  alfalfa\$ al  
fa\$ alf  $\sqcup$  eats  $\sqcup$  alfa  
falfa\$ alf  $\sqcup$  eats  $\sqcup$  al  
lf  $\sqcup$  eats  $\sqcup$  alfalfa\$ a  
lfa\$ alf  $\sqcup$  eats  $\sqcup$  alfa  
lfalfa\$ alf  $\sqcup$  eats  $\sqcup$  a  
s  $\sqcup$  alfalfa\$ alf  $\sqcup$  eat  
ts  $\sqcup$  alfalfa\$ alf  $\sqcup$  ea

# BWT Encoding Example

$S = \text{alf} \sqcup \text{eats} \sqcup \text{alfalfa\$}$

- ① Write all cyclic shifts
- ② Sort cyclic shifts
- ③ Extract last characters from sorted shifts

$C = \text{asff\$f} \sqcup \text{e} \sqcup \text{lll} \text{aaata}$

\$alf  $\sqcup$  eats  $\sqcup$  alfalfa a  
 $\sqcup$  alfalfa \$ alf  $\sqcup$  eat s  
 $\sqcup$  eats  $\sqcup$  alfalfa \$ al f  
a \$ alf  $\sqcup$  eats  $\sqcup$  alfal f  
alf  $\sqcup$  eats  $\sqcup$  alfalfa \$  
alfa \$ alf  $\sqcup$  eats  $\sqcup$  al f  
alfalfa \$ alf  $\sqcup$  eats  $\sqcup$   
ats  $\sqcup$  alfalfa \$ al f  $\sqcup$  e  
eats  $\sqcup$  alfalfa \$ al f  $\sqcup$   
f  $\sqcup$  eats  $\sqcup$  alfalfa \$ al  
fa \$ alf  $\sqcup$  eats  $\sqcup$  alfa l  
fal fa \$ alf  $\sqcup$  eats  $\sqcup$  al  
lf  $\sqcup$  eats  $\sqcup$  alfalfa \$ a  
lfa \$ alf  $\sqcup$  eats  $\sqcup$  alfa  
lfalfa \$ alf  $\sqcup$  eats  $\sqcup$  a  
s  $\sqcup$  alfalfa \$ alf  $\sqcup$  eat t  
ts  $\sqcup$  alfalfa \$ alf  $\sqcup$  ea

# BWT Encoding Example

$S = \text{alf} \sqcup \text{eats} \sqcup \text{alfalfa\$}$

- ① Write all cyclic shifts
- ② Sort cyclic shifts
- ③ Extract last characters from sorted shifts

$C = \text{asff\$f} \sqcup \text{e} \sqcup \text{lll} \text{aaata}$

\$alf  $\sqcup$  eats  $\sqcup$  alfalfa  
 $\sqcup$  alfalfa\$alf  $\sqcup$  eats  
 $\sqcup$  eats  $\sqcup$  alfalfa\$alf  
a\$alf  $\sqcup$  eats  $\sqcup$  alfalfa  
alf  $\sqcup$  eats  $\sqcup$  alfalfa\$  
alfa\$alf  $\sqcup$  eats  $\sqcup$  alf  
alfalfa\$alf  $\sqcup$  eats  $\sqcup$   
ats  $\sqcup$  alfalfa\$alf  $\sqcup$  e  
eats  $\sqcup$  alfalfa\$alf  $\sqcup$   
f  $\sqcup$  eats  $\sqcup$  alfalfa\$al  
fa\$alf  $\sqcup$  eats  $\sqcup$  alfa  
falfa\$alf  $\sqcup$  eats  $\sqcup$  al  
lf  $\sqcup$  eats  $\sqcup$  alfalfa\$a  
lfa\$alf  $\sqcup$  eats  $\sqcup$  alfa  
lfalfa\$alf  $\sqcup$  eats  $\sqcup$  a  
s  $\sqcup$  alfalfa\$alf  $\sqcup$  eat  
ts  $\sqcup$  alfalfa\$alf  $\sqcup$  ea

**Observe:** Substring **alf** occurs three times and causes runs **lll** and **aaa** in  $C$  (why?)

# Fast Burrows-Wheeler Encoding

$S = \text{alf} \sqcup \text{eats} \sqcup \text{alfalfa\$}$

# BWT Decoding

**Idea:** Given  $C$ , we can reconstruct the *first* and *last column* of the array of cyclic shifts by sorting.

$C = \text{ard\$rcaaaabb}$

- ① Last column:  $C$
- ② First column:  $C$  sorted
- ③ Disambiguate by row-index

Can argue: Repeated characters are in the same order in the first and the last column (the sort was *stable*).

# BWT Decoding

*BWT::decoding( C[0..n - 1], S )*

$C$  : string of characters over alphabet  $\Sigma_S$ ,  $S$ : output-stream

1.  $A \leftarrow$  array of size  $n$  // leftmost column
2. **for**  $i = 0$  to  $n - 1$
3.      $A[i] \leftarrow (C[i], i)$  // store character and index
4. Stably sort  $A$  by character
5. **for**  $j = 0$  to  $n - 1$  // where is the \$-char?
6.     if  $C[j] = \$$  **break**
7. **repeat**
8.      $S.append(\text{character stored in } A[j])$
9.      $j \leftarrow \text{index stored in } A[j]$
10. **until** we have appended \$

# BWT Overview

**Encoding cost:**  $O(n \log n)$

- Read encoding from the suffix array.
- In practice MSD radix sort is good enough (but worst-case  $\Theta(n^2)$ ).

**Decoding cost:**  $O(n + |\Sigma_S|)$  (faster than encoding)

Encoding and decoding both use  $O(n)$  space.

They need ***all*** of the text (no streaming possible). BWT is a **block compression method**.

BWT tends to be slower than other methods, but (combined with MTF, modified RLE and Huffman) gives better compression.

# Compression summary

| Huffman                         | Run-length encoding                | Lempel-Ziv-Welch                    | bzip2 (uses Burrows-Wheeler)    |
|---------------------------------|------------------------------------|-------------------------------------|---------------------------------|
| variable-length                 | variable-length                    | fixed-length                        | multi-step                      |
| single-character                | multi-character                    | multi-character                     | multi-step                      |
| 2-pass, must send dictionary    | 1-pass                             | 1-pass                              | not streamable                  |
| 60% compression on English text | bad on text                        | 45% compression on English text     | 70% compression on English text |
| optimal 01-prefix-code          | good on long runs (e.g., pictures) | good on English text                | better on English text          |
