## ALL PAIRS SHORTEST PATHS (APSP) PROBLEM

**Instance:** A directed graph  $G = (V, E)$ , and a weight matrix  $W$ , where  $W[i, j]$  denotes the weight of edge  $ij$ , for all  $i, j \in V, i \neq j$ .

**Find:** For all pairs of vertices  $u, v \in V, u \neq v$ , a directed path  $P$  from  $u$  to  $v$  such that

$$w(P) = \sum_{ij \in P} W[i, j]$$

is minimized.

We allow edges to have negative weights, but we assume there are no negative-weight directed cycles in  $G$ .

2

We use the following conventions for the weight matrix  $W$ :

$$W[i, j] = \begin{cases} w_{ij} & \text{if } (i, j) \in E \\ 0 & \text{if } i = j \\ \infty & \text{otherwise.} \end{cases}$$

from: 

	a	b	c	d
a		0	3	$\infty$
b			0	12
c				0
d				

 to: 

	a	b	c	d
a		0	3	$\infty$
b			0	12
c				0
d				

3

### EASY SOLUTION

Run Bellman-Ford  $n$  times, once for each possible source

**Output:** Matrix  $D$  of shortest path lengths

	a	b	c	d
a		0	3	15
b			0	12
c				0
d				

Complexity  $O(n^2m)$ . (Could be  $O(n^3)$ .) Can we do better?

4

### A Dynamic Programming Approach

Suppose we successively consider paths of length  $1, 2, \dots, n-1$ . Let  $L_m[i, j]$  denote the minimum-weight  $(i, j)$ -path having at most  $m$  edges.

We want to compute  $L_{n-1}$ .

Base case:  $L_1 = W$

General case: How to express solution in terms of optimal solutions to subproblems?

Express shortest path with  $m$  edges in terms of shortest path(s) with  $< m$  edges?

For  $m \geq 2$ ,

$$L_m[i, j] = \min\{L_{m-1}[i, k] + L_1[k, j] : 1 \leq k \leq n\}.$$

Problem: we don't know the predecessor of  $j$  on the optimal path  $P$ . Try all possible predecessors  $k$ .

Arguing optimal substructure: Let  $P'$  be minimum weight  $(i, j)$ -path with  $\leq m$  edges. Let  $k$  be the predecessor of  $j$  on path  $P'$ . Then  $P'$  = minimum weight  $(i, k)$ -path with  $\leq m-1$  edges (or could shrink  $w(P')$ ; contral)

5

**Algorithm:** *FairlySlowAllPairsShortestPath*( $W$ )

```

L1 ← W
for m ← 2 to n-1
  for i ← 1 to n
    for j ← 1 to n
      ℓ ← ∞
      for k ← 1 to n
        do ℓ ← min(ℓ, L_{m-1}[i, k] + W[k, j])
      L_m[i, j] ← ℓ
return (L_{n-1})
    
```

Time complexity?  $O(n^3)$

Space complexity is a bit subtle...

Home exercise: do we need to keep both  $L_m$  and  $L_{m-1}$ ? Or can we reuse  $L_{m-1}$  directly as our  $L_m$  array, and modify it in-place?

To compute  $L_m$ , only need  $W$  and  $L_{m-1}$ . No need to keep  $L_2, \dots, L_{m-2}$ . So space is  $O(|W| + |L_{m-1}| + |L_{m-1}|) = O(|L_{m-1}|) = O(n^2)$ .

Note: this is asymptotically the same as input size for dense graphs where  $|E| \in \Theta(|V|^2)$ .

6

### BETTER SOLUTION: SUCCESSIVE DOUBLING

The idea is to construct  $L_1, L_2, L_4, \dots, L_{2^t}$ , where  $t$  is the smallest integer such that  $2^t \geq n - 1$ .

Initialization:  $L_1 = W$  (as before).

Arguing optimal substructure: Let  $P$  = minimum weight  $(i, j)$ -path with  $\leq 2m$  edges and  $k$  = midpoint node of  $P$ .

Then  $P = P_1 \cup P_2$ , where:  $P_1$  is the minimum weight  $(i, k)$ -path with  $\leq m$  edges and  $P_2$  is the minimum weight  $(k, j)$ -path with  $\leq m$  edges (or else we could improve  $P$  by improving  $P_1$  or  $P_2$ ).

Updating: For  $m \geq 1$ ,  $L_{2m}[i, j] = \min\{L_m[i, k] + L_m[k, j] : 1 \leq k \leq n\}$ . Don't know which node is midpoint of  $P$ , so try all  $k$ ...

### Second Solution: Successive Doubling

Algorithm: *FasterAllPairsShortestPath(W)*

```

L1 ← W
m ← 1
while m < n - 1
  for i ← 1 to n
    for j ← 1 to n
      ℓ ← ∞
      for k ← 1 to n
        do ℓ ← min{ℓ, Lm[i, k] + Lm[k, j]}
        L2m[i, j] ← ℓ
      m ← 2m
  return (Lm)
  
```

Complexity analysis:  $O(n^3 \log n)$  runtime,  $O(n^2)$  space.

### SUMMARY & WHAT'S NEXT

- First solution: sub-problem is a path to the predecessor node
  - Optimality: try all possible predecessor nodes  $k$
- Second solution: sub-problems are paths to/from the midpoint node
  - Optimality: try all possible midpoint nodes  $k$
- Third solution: sub-problems are paths in which all interior nodes are in  $\{1..k-1\}$ 
  - I.e., we restrict paths to using a prefix of all nodes
  - Optimality: try all ways to use new node  $k$  as an interior node

### THIRD SOLUTION: FLOYD-WARSHALL

Let  $D_k[i, j]$  denote the length of the minimum-weight path  $i \rightarrow j$  in which all interior nodes are in the set  $\{1, \dots, k\}$ . We want to compute  $D_n$ .

Let  $P$  be a min-weight  $(i, j)$ -path in which all interior nodes are in  $\{1, \dots, k\}$ .

Case 1:  $k$  is not used in  $P$ . Interior nodes are all in  $\{1, \dots, k-1\}$ . Then  $D_k[i, j] = D_{k-1}[i, j]$ .

Case 2:  $k$  is used in  $P$ . Interior nodes are all in  $\{1, \dots, k-1\}$ . Then  $D_k[i, j] = D_{k-1}[i, k] + D_{k-1}[k, j]$ .

Optimal solution: interior nodes are all in  $\{1, \dots, k\}$ .

Because  $P$  would then contain a cycle, and the cycle cannot make  $P$  shorter. So there must be an equivalent or better  $P$  without a cycle.

more formal proof in bonus slides

### FLOYD-WARSHALL ALGORITHM

- Let  $D_k[i, j]$  denote the length of the minimum-weight  $(i, j)$ -path in which all interior nodes are in the set of nodes  $\{1 \dots k\}$ .
- Base case:  $D_0 = W$
- Recurrence:  $D_k[i, j] = \min\{D_{k-1}[i, j], D_{k-1}[i, k] + D_{k-1}[k, j]\}$

```

FloydWarshall(W[1..n, 1..n])
1  D0 ← copy of weight matrix W
2  D1 ← new n × n matrix
3  Dlast ← pointer to D0
4  Dcurr ← pointer to D1
5  for k ← 1..n
6  for i ← 1..n
7  for j ← 1..n
8  Dcurr[i, j] ← min(Dlast[i, j], Dlast[i, k] + Dlast[k, j])
9  swap pointers Dlast and Dcurr
10 return Dlast
  
```

Time complexity? Space complexity? This returns distances. Can reconstruct paths from this.

### EXAMPLE

$D_0 = \begin{pmatrix} 0 & 3 & \infty & \infty \\ \infty & 0 & 12 & 5 \\ 4 & \infty & 0 & -1 \\ 2 & -4 & \infty & 0 \end{pmatrix}$ 
 $D_1 = \begin{pmatrix} 0 & 3 & \infty & \infty \\ \infty & 0 & 12 & 5 \\ 4 & 7 & 0 & -1 \\ 2 & -4 & \infty & 0 \end{pmatrix}$

$D_2 = \begin{pmatrix} 0 & 3 & 15 & 8 \\ \infty & 0 & 12 & 5 \\ 4 & 7 & 0 & -1 \\ 2 & -4 & 8 & 0 \end{pmatrix}$ 
 $D_3 = \begin{pmatrix} 0 & 3 & 15 & 8 \\ 16 & 0 & 12 & 5 \\ 4 & 7 & 0 & -1 \\ 2 & -4 & 8 & 0 \end{pmatrix}$

$D_4 = \begin{pmatrix} 0 & 3 & 15 & 8 \\ 7 & 0 & 12 & 5 \\ 1 & -5 & 0 & -1 \\ 2 & -4 & 8 & 0 \end{pmatrix}$

**STABLE MATCHING PROBLEM**  
(SOLVED WITH A GREEDY GRAPH ALGORITHM)

13

**Problem 4.6**  
**Stable Matching**

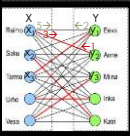

**Instance:** Two sets of size  $n$ , say  $X = \{x_1, \dots, x_n\}$  and  $Y = \{y_1, \dots, y_n\}$ . Each  $x_i$  has a preference ranking of the elements in  $Y$ , and each  $y_j$  has a preference ranking of the elements in  $X$ .  $\text{pref}(x_i, j) = y_k$  if  $y_k$  is the  $j$ -th favourite element of  $Y$  of  $x_i$ , and  $\text{pref}(y_j, i) = x_k$  if  $x_k$  is the  $i$ -th favourite element of  $X$  of  $y_j$ .

**Find:** A matching of the sets  $X$  and  $Y$  such that there does not exist a pair  $(x_i, y_j)$  which is not in the matching, but where  $x_i$  and  $y_j$  prefer each other to their existing matches. A matching with this property is called a **stable matching**.

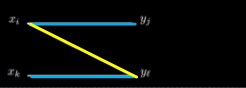

Real-world examples (1950s):

- Matching medical interns to hospitals.
- Matching organs to patients requiring transplants.

The 2012 Nobel Prize in economics was awarded to Roth and Shapley for their work in the "theory of stable allocation and the practice of market design".

An example of an instability. Suppose  $x_i$  is matched with  $y_j$ ,  $x_k$  is matched with  $y_l$ ,  $x_i$  prefers  $y_l$  to  $y_j$ , and  $y_l$  prefers  $x_i$  to  $x_k$ .

**Overview of the Gale-Shapley Algorithm**

Elements of  $X$  propose to elements of  $Y$ .

If  $y_j$  accepts a proposal from  $x_i$ , then the pair  $\{x_i, y_j\}$  is **matched**. An unmatched  $y_j$  must accept a proposal from any  $x_i$ .

If  $\{x_i, y_j\}$  is a matched pair, and  $y_j$  subsequently receives a proposal from  $x_k$ , where  $y_j$  prefers  $x_k$  to  $x_i$ , then  $y_j$  accepts and the pair  $\{x_i, y_j\}$  is replaced by  $\{x_k, y_j\}$ .

If  $\{x_i, y_j\}$  is a matched pair, and  $y_j$  subsequently receives a proposal from  $x_k$ , where  $y_j$  prefers  $x_i$  to  $x_k$ , then  $y_j$  rejects and nothing changes.

A matched  $y_j$  never becomes unmatched.

An  $x_i$  might make a number of proposals (up to  $n$ ); the order of the proposals is determined by  $x_i$ 's preference list.

**Algorithm: Gale-Shapley( $X, Y, \text{pref}$ )**

$\text{Match} \leftarrow \emptyset$

**while** there exists an unmatched  $x_i$

  let  $y_j$  be the next element in  $x_i$ 's preference list

**if**  $y_j$  is not matched

**then**  $\text{Match} \leftarrow \text{Match} \cup \{x_i, y_j\}$

**do**

    suppose  $\{x_k, y_j\} \in \text{Match}$

**if**  $y_j$  prefers  $x_i$  to  $x_k$

**then**  $\text{Match} \leftarrow \text{Match} \setminus \{x_k, y_j\} \cup \{x_i, y_j\}$

      comment:  $x_k$  is now unmatched

**return** ( $\text{Match}$ )

**EXAMPLE:**

Suppose we have the following preference lists:

$x_1 : y_2 > y_3 > y_1$        $y_1 : x_1 > x_2 > x_3$   
 $x_2 : y_1 > y_3 > y_2$        $y_2 : x_2 > x_3 > x_1$   
 $x_3 : y_1 > y_2 > y_3$        $y_3 : x_3 > x_2 > x_1$

The Gale-Shapley algorithm could be executed as follows:

proposal	result	Match
$x_1$ proposes to $y_2$	$y_2$ accepts	$\{x_1, y_2\}$
$x_2$ proposes to $y_1$	$y_1$ accepts	$\{x_1, y_2\}, \{x_2, y_1\}$
$x_3$ proposes to $y_1$	$y_1$ rejects	
$x_3$ proposes to $y_2$	$y_2$ accepts	$\{x_3, y_2\}, \{x_2, y_1\}$
$x_1$ proposes to $y_3$	$y_3$ accepts	$\{x_3, y_2\}, \{x_2, y_1\}, \{x_1, y_3\}$

### Proof of Correctness

First we need to show that the algorithm always terminates, i.e., it is impossible that an unmatched  $x_i$  has proposed to every  $y_j$ .  
 Termination of the algorithm: Once an element of  $Y$  is matched, they are never unmatched. If  $x_i$  has proposed to every  $y_j$ , then every  $y_j$  is matched. But then every element of  $X$  is matched, which is a contradiction.

- So the algorithm terminates, and each  $x_i$  is matched with some  $y_j$ .
- Need to argue the matching is **stable** (i.e., optimal)
- That is, no  $x_i$  and  $y_j$  prefer **each other more** than their current partners

To prove that the algorithm terminates with a stable matching: Suppose there is an instability:  $x_i$  is matched with  $y_j$ ,  $x_k$  is matched with  $y_l$ ,  $x_i$  prefers  $y_l$  to  $y_j$  and  $y_l$  prefers  $x_i$  to  $x_k$ .

Observe:  $x_i$  proposes to  $y_l$  before proposing to  $y_j$

There three cases to consider:

- (1)  $y_l$  rejected  $x_i$ 's proposal.   
 Then  $y_l$  should end up matched with  $x_k$ . Contradiction!
- (2)  $y_l$  accepted  $x_i$ 's proposal, but later accepted another proposal.   
 Other proposal must be to someone better. Contradiction!
- (3)  $y_l$  accepted  $x_i$ 's proposal, and did not accept any subsequent proposal.   
 Implies  $y_l$  already matched with someone better than  $x_i$ . And  $y_l$  can only change to even **better** partners, so  $y_l$ 's current partner is better than  $x_i$ . Contradicts our assumption that this instability exists!

All three cases are impossible, so assumption is wrong. There **cannot** be an instability!

### COMPLEXITY

It is obvious that the number of iterations is at most  $n^2$  since every  $x_i$  proposes at most once to every  $y_j$ .

The average number of iterations is  $\Theta(n \log n)$  (but we will not prove this).

But how much time does it take per iteration?

Algorithm: *Gale-Shapley*( $X, Y, pref$ )

Depends on how we implement the algorithm...

```

Match ← ∅
while there exists an unmatched  $x_i$ 
do
  let  $y_j$  be the next element in  $x_i$ 's preference list
  if  $y_j$  is not matched
  then Match ← Match ∪ { $x_i, y_j$ }
  else
    suppose { $x_k, y_j$ } ∈ Match
    if  $y_j$  prefers  $x_i$  to  $x_k$ 
    then Match ← Match \ { $x_k, y_j$ } ∪ { $x_i, y_j$ }
    comment:  $x_k$  is now unmatched
return Match
    
```

Maintain a **queue** of unmatched  $x$  elements

Simple **list** of preferences

Want to know **who**  $y_j$  is matched with

Maintain **arrays** of matches. If  $x_i$  and  $y_j$  are matched then  $M_x[i] = j$  and  $M_y[j] = i$  (Initially  $M_x[i], M_y[j] = 0$ )

Want to **quickly** look up  $y_j$ 's **rank** for  $x_i$  and  $x_k$

Construct an **array**  $R[j, i]$  containing the **rank** of  $x_i$  in  $y_j$ 's preference list

I.e., want  $R[j, i] = k$  if  $x_i$  is  $y_j$ 's  **$k$ -th favourite** partner

So, we get  $O(1)$  time per iteration, and  $O(n^2)$  time in total

$O(n^2)$  preprocessing

Allows comparing two ranks in  $O(1)$  time!

Exercise: try writing pseudocode for this implementation

### FORMULATING GRAPH PROBLEMS

Graphs are a very important formalism in computer science. Efficient algorithms are available for many important problems:

- ▶ exploration,
- ▶ shortest paths,
- ▶ minimum spanning trees, etc.

If we formulate a problem as a graph problem, chances are that an efficient non-trivial algorithm for solving the problem is known.

Some problems have a natural graph formulation.

- ▶ For others we need to choose a less intuitive graph formulation.
- ▶ Some problems that do not seem to be graph problems at all can be formulated as such.

### The RootBear Problem:

Suppose we have a canyon with perpendicular walls on either side of a forest.

- ▶ We assume a north wall and a south wall.

Viewed from above we see the A&W RootBear attempting to get through the canyon.

- ▶ We assume trees are represented by points.
- ▶ We assume the bear is a circle of given diameter  $d$ .
- ▶ We are given a list of coordinates for the trees.

Find an algorithm that determines whether the bear can get through the forest.

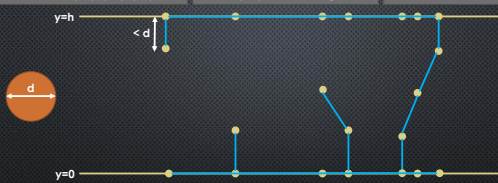

25

For each input point  $(x,y)$ :  
add vertices  $(x,0), (x,h), (x,y)$  to  $V$

For all pairs of vertices  $u, v$  in  $V$ :  
if  $\text{dist}(u,v) < d$ , add edge  $uv$

Also add edges between all vertices on each canyon wall

Bear **cannot** get through the canyon if North and South walls are **connected**

Test connectivity using BFS from any point on the North wall, and checking if any point on the South wall is visited.

Exercise: what if each tree had radius  $r$ ?

26

### Reliable network routing:

- ▶ Suppose we have a computer network with many links.
- ▶ Every link has an assigned reliability.

  - \* The reliability is a probability between 0 and 1 that the link will operate correctly.

- ▶ Given nodes  $u$  and  $v$ , we want to choose a route between nodes  $u$  and  $v$  with the highest reliability.

  - \* The reliability of a route is a product of the reliabilities of all its links.

Reliability of path  $a \rightarrow b \rightarrow c \rightarrow d$ :  
 $0.5 * 0.9 * 0.75 = 0.3375$

Higher reliability via path  $a \rightarrow b \rightarrow d$ :  
 $0.5 * 0.8 = 0.4$

27

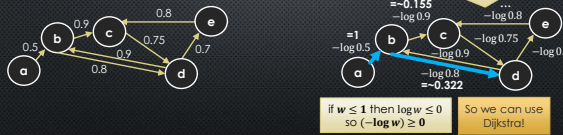

Can we turn this into a **shortest path** problem?

Problem 1: need **product** of weights **not sum**  
Use **logs** to turn product of weights into a **sum**.  
Recall:  $\log xy = \log x + \log y$ . So  $\log \prod w = \sum \log w$ .

$\log \prod \frac{1}{w} = \log \frac{1}{\prod w} = \log 1 - \log \prod w = -\log \prod w$   
 $= -\sum \log w = \sum (-\log w)$ . ← Want to minimize this!

Shortest path **minimizes** a sum of weights  $\sum w$   
Problem 2: want to **maximize** the product  
A path  $P$  has **maximum**  $\prod w$   
IFF it has **maximum**  $\log \prod w$   
IFF it has **minimum**  $\log \prod \frac{1}{w}$

**Solution:** create a new graph where each weight  $w$  is replaced with weight  $(-\log w)$

if  $w \leq 1$  then  $\log w \leq 0$   
so  $(-\log w) \geq 0$  So we can use Dijkstra!

28

29

## A MORE FORMAL OPTIMALITY ARGUMENT FOR YOUR NOTES

By induction: **suppose  $D_{m-1}(i,j)$  is correct** for all  $i,j$ . We show  $D_m(i,j)$  is correct. (Base case  $D_0(i,j)$  is left as an exercise)

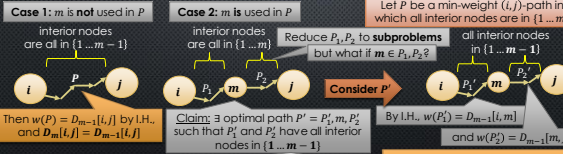

**Case 1:  $m$  is not used in  $P$**   
interior nodes are all in  $\{1 \dots m-1\}$

**Case 2:  $m$  is used in  $P$**   
interior nodes are all in  $\{1 \dots m\}$

Reduce  $P_1, P_2$  to subproblems but what if  $m \in P_1, P_2$ ?

all interior nodes in  $\{1 \dots m-1\}$

Consider  $P'$

Then  $w(P) = D_{m-1}(i,j)$  by I.H., and  $D_m(i,j) = D_{m-1}(i,j)$

Claim:  $\exists$  optimal path  $P' = P'_1, m, P'_2$  such that  $P'_1$  and  $P'_2$  have all interior nodes in  $\{1 \dots m-1\}$

By I.H.,  $w(P'_1) = D_{m-1}(i,m)$  and  $w(P'_2) = D_{m-1}(m,j)$

And  $w(P'_1) + w(P'_2) = D_{m-1}(i,m) + D_{m-1}(m,j) = D_m(i,j)$

(details in side notes) (if  $m$  appears twice in  $P'$ , it creates a cycle which can be removed to get  $P'$  with some or better weight)

30
