Module 11: Additional Topics

Graph Theory and Applications

Topics:

• Introduction to Graph Theory
• Representing (undirected) graphs
• Basic graph algorithms
Consider the following:

- **Traveling Salesman Problem (TSP):** Given N cities and the distances between them, find the shortest path to visit all cities and return to the start.
What does the TSP have in common with the following problems?

• Placement of new fire stations in a city to provide best coverage to all residents
• Ranking of "importance" of web pages by Google's PageRank algorithm
• Scheduling of final exams so they do not conflict
• Arranging components on a computer chip
• Analyzing strands of DNA
• Binary Search Trees
They all fall within the field of **GRAPH THEORY**

Non-conflicting exams

PageRank Algorithm
Undirected Simple Graphs

An undirected simple graph $G$ is a set $V$, of vertices, and a set $E$, of unordered distinct pairs from $V$, called edges. We write $G=(V,E)$. 
Graph Terminology

• If \((v_k, v_p)\) is an edge, we say that \(v_k\) and \(v_p\) are neighbours, and are adjacent. Note that \(k\) and \(p\) must be different.

• The number of neighbours of a vertex is also called its degree

• A sequence of nodes \(v_1, v_2, ..., v_k\) is a path of length \(k-1\) if \((v_1, v_2), (v_2, v_3),..., (v_{k-1}, v_k)\) are all edges
  – If \(v_1 = v_k\), this is called a cycle

• A graph \(G\) is connected if there exists a path through all vertices in \(G\)
Interesting Results on Graphs

Let $n$ = number of vertices, and $m$ = number of edges:

1. $m \leq n(n - 1)/2$
2. The number of graphs on $n$ vertices is $2^{n(n-1)/2}$
3. The sum of the degrees over all vertices is $2m$. 
How can we store information about graphs in Python?

• We need to store labels for the vertices
  – These could be strings or integers
• We need to store both endpoints using the labels on the vertices.

• We will consider three different implementations for undirected, unweighted graphs
Implementation 1: Vertex and Edge Lists

- \( V = [v_1, v_2, v_3, ..., v_m], \)
- \( E = [e_1, e_2, e_3, ..., e_m], \) where edge \( e_j = [a, b] \) when vertices \( a \) and \( b \) are connected by an edge

\[ V = [6, 4, 5, 3, 2, 1] \]
\[ E = [[6, 4], [4, 5], [4, 3], [3, 2], [5, 2], [1, 2], [5, 1]] \]
Implementation 2: Adjacency list

- For each vertex:
  - Store the labels on its neighbours in a list
- We will use a dictionary
  - Keys: labels of vertices
  - Recall: integers or strings can be keys
  - Associated values: List of neighbours (adjacent vertices)
Example:

\{1: [2, 5], \\
2: [1, 3, 5], \\
3: [2, 4], \\
4: [3, 5, 6], \\
5: [1, 2, 4], \\
6: [4] \}
Implementation 3: Adjacency Matrix

• For simplicity, assume vertices are labelled $0, \ldots, n-1$

• Create an $n$ by $n$ matrix for $G$

• If there is an edge connecting $i$ and $j$:
  – Set $G[i][j] = 1$,
  – Set $G[j][i] = 1$

• Otherwise, set these values to 0
Example:

G:

<table>
<thead>
<tr>
<th>vertex</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[ 0, 1, 0, 0, 1, 0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>[ 1, 0, 1, 0, 1, 0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>[ 0, 1, 0, 1, 0, 1]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>[ 0, 0, 1, 0, 1, 1]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>[ 1, 1, 0, 1, 0, 0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>[ 0, 0, 0, 1, 0, 0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Comparing the implementations on simple tasks

• Determine if two vertices are neighbours.
• Find all the neighbours of a vertex.

Which implementation to use?
• We'll use the adjacency list (a good case could also be made for the adjacency matrix).
Graph Traversals

• Determine all vertices of G that can be reached from a starting vertex
• There can be different types of traversals
• If you find all vertices starting from v, the graph is \textit{connected}
• If not all vertices can be reached, a \textit{connected component} containing v has been found
• Must determine a way to ensure we do not cycle indefinitely
Applications of traversals

• Finding path between two vertices
• Finding connected components
• Tracing garbage collection in programs (managing memory)
• Shortest path between two points
• Planarity testing
• Solving puzzles like mazes
• Graph colouring
One approach:
Breadth-first search Traversal (bfs)

• Choose a starting point $v$
• Visit all the neighbours of $v$
• Then, visit all of the neighbours of the neighbours of $v$, etc.
• Repeat until all reachable vertices are visited
• Need some way to avoid visiting edges more than once
• Note: there may be more than one bfs ordering of a graph, starting from $v$. 
Sample bfs orders

- A, C, E, B, I, F, G, D, H
- A, E, C, I, B, H, D, G, F
- B, E, F, G, D, I, A, H, C
- B, D, E, F, G, I, A, C, H
- H, I, C, B, D, A, E, F, G

plus more ...
Implementing bfs

• We will look at one implementation.
• Assumes an adjacency list representation.
• We use several lists:
  – all includes all "visited" vertices
    • Vertices are appended to the end
  – Q includes vertices waiting to be "visited" (it will grow and shrink as the algorithm progresses)
    • Vertices are appended to the end and removed from the front of Q
Implementation of bfs traversal

def bfs(graph, v):
    all = []
    Q = []
    Q.append(v)
    while Q != []:
        v = Q.pop(0)
        all.append(v)
        for n in graph[v]:
            if n not in Q and n not in all:
                Q.append(n)
    return all
Starting bfs from 0 (1)

• Start from v=0
• all = []
• Q = [0]
  – v = 0
  – all = [0]
  – Neighbours of 0: 1,4
    • Q = [1,4]
Continuing bfs (2)

- $Q = [1, 4]$
- $v = 1$
- $all = [0,1]$
- Neighbours of 1: 0, 2, 3
  - $Q = [4, 2, 3]$
Continuing bfs (3)

• Q: [4, 2, 3]
• v = 4
• all = [0,1,4]
• Neighbours of 4: 0,3
  – No vertices added to Q
• Q= [2,3]
• v = 2
• all = [0,1,4,2]
• Neighbours of 2: 1,6 → Q = [3,6]
Continuing bfs (4)

- Q: [3, 6]
- v = 3
- all = [0,1,4,2,3]
- Neighbours of 3: 1,4,5
  - Q = [6,5]
- Q = [6, 5]
- v = 6
- all = [0,1,4,2,3,6]
- Neighbours of 6: 2,7,8
  - Q = [5,7,8]
Continuing bfs (5)

- Q: [5, 7, 8]
- v = 5
- all = [0,1,4,2,3,6,5]
- Neighbours of 5: 3,8 (Q unchanged)
- Q = [7,8]
- v = 7
- all = [0,1,4,2,3,6,5,7]
- Neighbours of 7: 6 (Q unchanged)
- Q = [8]
- v = 8
- all = [0,1,4,2,3,6,5,7,8]
- Neighbours of 8: 5,6 (Q unchanged)
- Q is empty
Another approach: depth-first traversal (dfs)

• Choose a starting point v
• Proceed along a path from v as far as possible
• Then, backup to previous (most recently visited) vertex, and visit its unvisited neighbour (this is called backtracking)
  – Repeat while unvisited, reachable vertices remain
• Note: there may be more than one dfs ordering of a graph, starting from v.
Sample dfs orders

- A, C, I, H, B, F, D, G, E
- A, E, B, G, D, I, H, C, F
- B, F, G, D, I, C, A, E, H
- H, I, B, F, G, D, E, A, C

plus more ...
Implementing dfs

• We will look at one implementation.
• Assumes an adjacency list representation.
• We use several lists:
  – all includes all "visited" vertices  
    • Vertices are appended to the end  
  – S includes vertices waiting to be "visited" (it will grow and shrink as the algorithm progresses)  
    • Vertices are appended to the end and removed from the end of S as well
A depth first search traversal solution

def dfs(graph, v):
    all = []
    S = [v]
    while S != []:
        v = S.pop()
        if v not in all:
            all.append(v)
            for w in graph[v]:
                if w not in all:
                    S.append(w)
    return all
Breadth first vs depth first Searches

• Both need an additional list to store needed information:
  – BFS uses Q:
    • Add to the end and remove from the front
    • Called a Queue
  – DFS uses S:
    • Add to the end and remove from the end
    • Called a Stack
  – Stacks and Queues are both very useful in CS
Extension: Weighted edges

- Each edge has an associated weight. It might represent:
  - Distance between cities
  - Cost to move between locations
  - Capacity of a route
  - Probability of moving from one web page to another
Adjust adjacency list to include weights

• Adjust our adjacency list to store weights with each edge

• \{ 1: [[2,2], [4,5]],
    2: [[1,2], [3,14],
        [4,5], [5,4]],
    3: [[2,14], [5,34]],
    4: [[1,5], [2,5], [5,58]],
    5: [[2,4], [3,34], [4,58]] \}
Other types of graphs

- Edges can be directed – from one vertex to another
- Directed edges can have weights as well
- **Exercise:** Think about how directions change our representations
Goals of Module 11

• Understand basic graph terminology
• Understand representation of graphs in Python
• Understand breadth-first and depth-first search traversals
