Outline

An introduction to concurrent programming, with an emphasis on language constructs. Major topics include: exceptions, coroutines, atomic operations, critical sections, mutual exclusion, semaphores, high-level concurrency, deadlock, interprocess communication, process structuring on shared memory architectures. Students learn how to structure, implement and debug complex control-flow.

1 Advanced Control Flow (Review)

• **Within** a routine, basic and advanced control structures allow virtually any control flow.

• **Multi-exit loop** (or mid-test loop) has one or more exit locations occurring within the body of the loop, not just top (while) or bottom (do-while):

```c
for ( ;; ) { // infinite loop, while ( true )
    ...
    if ( ... ) break; // middle exit
    ...
}  
```

condition reversed from while, outdent exit for readability

• Eliminates priming (duplicated) code necessary with while:

```c
cin >> d; // priming
while ( ! cin.fail() ) {
    ...
    cin >> d;
    ...
}  
```

• Eliminate `else` on loop exits:

```c
BAD   GOOD
for ( ;; ) {
    S1
    if ( C1 ) {
        S2
    } else {
        break;
    }
    S3
}  
```

```c
BAD   GOOD
for ( ;; ) {
    S1
    if ( ! C1 ) break;
    S2
}  
```

S2 is logically part of loop body not part of an if.

• Allow multiple exit conditions:

```c
bool flag1 = false, flag2 = false;
while ( ! flag1 & ! flag2 ) {
    S1
    if ( C1 ) flag1 = true;
    } else {
        S2
        if ( C2 ) flag2 = true;
    } else {
        S3
    }
}

if ( flag1 ) E1;
else E2;
```
• Eliminate flag variables used solely to affect control flow, i.e., variable does not contain data associated with computation.

• Flag variables are the variable equivalent to a goto because they can be set/reset/tested at arbitrary locations in a program.

1.1 Static multi-level exit

• Static multi-level exit exits multiple control structures where exit point is known at compile time.

• Labelled exit (break/continue) provides this capability:

```
\text{\L1: \{ // good eye\textendash;candy
... declarations ...
\L2: switch ( ... ) {
  \L3: for ( ... ) {
    ... break \L1; ... // exit block
    ... break \L2; ... // exit switch
    ... break \L3; ... // exit loop
  }
  ...
}
...
\}
...}
```

• Why is it good practice to label all exits?

• Eliminate all flag variables with multi-level exit!

```
\text{\texttt{\textbf{B1: for} ( i = 0; i < 10; i += 1 ) {}}}
\text{\texttt{\textbf{B2: for} ( j = 0; j < 10; j += 1 ) {}}}
\text{\texttt{... if ( ... ) break \texttt{B2}; // outdent}}
\text{\texttt{... // rest of loop}}
\text{\texttt{if ( ... ) break \texttt{B1}; // outdent}}
\text{\texttt{... // rest of loop}}
\text{\texttt{\} // for}}
\text{\texttt{... // rest of loop}}
\text{\texttt{\} // for}}

\text{\texttt{bool flag1 = false;}}
\text{\texttt{for ( i = 0; i < 10 && ! flag1; i += 1 ) {}}}
\text{\texttt{bool flag2 = false;}}
\text{\texttt{for ( j = 0; j < 10 && ! flag1 && ! flag2; j += 1 ) {}}}
\text{\texttt{... if ( ... ) flag2 = true;}}
\text{\texttt{else {}}}
\text{\texttt{... // rest of loop}}
\text{\texttt{if ( ... ) flag1 = true;}}
\text{\texttt{else {}}}
\text{\texttt{... // rest of loop}}
\text{\texttt{\} // if}}
\text{\texttt{\} // for}}
\text{\texttt{if ( ! flag1 ) {}}}
\text{\texttt{... // rest of loop}}
\text{\texttt{\} // if}}
\text{\texttt{\} // for}}
```
• Occasionally a flag variable is necessary!

• E.g., retain state from one inner lexical (static) scope to another:

```c
int val; bool valDefault = false;
switch ( argv ) {
  ...
  case 3:
    if ( strcmp( argc[4], "d" ) != 0 ) valDefault = true; // default ?
    else val = stoi( argc[4] ); // value
  ...
} // switch
for ( ;; ) {
  ...
  if ( valDefault ) // do something
    else // do another
      ...
} // for
```

• Other uses of multi-level exit to remove duplicate code:

<table>
<thead>
<tr>
<th>duplication</th>
<th>no duplication</th>
</tr>
</thead>
<tbody>
<tr>
<td>if ( C1 ) {</td>
<td></td>
</tr>
<tr>
<td>S1;</td>
<td>C: {</td>
</tr>
<tr>
<td>if ( C2 ) {</td>
<td></td>
</tr>
<tr>
<td>S2;</td>
<td>if ( C1 ) {</td>
</tr>
<tr>
<td>if ( C2 ) {</td>
<td></td>
</tr>
<tr>
<td>S2;</td>
<td>S1;</td>
</tr>
<tr>
<td>if ( C3 ) {</td>
<td></td>
</tr>
<tr>
<td>S3;</td>
<td>if ( C2 ) {</td>
</tr>
<tr>
<td>} else</td>
<td>if ( C3 ) {</td>
</tr>
<tr>
<td>S4;</td>
<td>S3;</td>
</tr>
<tr>
<td>} else</td>
<td>break C;</td>
</tr>
<tr>
<td>S4;</td>
<td>goto C;</td>
</tr>
<tr>
<td>} else</td>
<td>}</td>
</tr>
<tr>
<td>S4;</td>
<td>}</td>
</tr>
</tbody>
</table>

• Normal and labelled `break` are a `goto` with limitations:

1. Cannot loop (only forward branch) ⇒ only loop constructs branch back.
2. Cannot branch `into` a control structure.

• **Only use `goto` to perform static multi-level exit, e.g., simulate labelled `break` and `continue`.

### 1.2 Dynamic Memory Allocation

• Stack allocation eliminates explicit storage-management and often more efficient than heap allocation — “Use the STACK, Luke Skywalker.”
• These are the situations where dynamic allocation (heap) is necessary:

1. When a variable’s storage must outlive the block in which it is allocated.

   ```
   Type * rtn(...) {
     Type * tp = new Type; // MUST USE HEAP
     // initialize/compute using tp
     return tp; // storage outlives block
   }
   // tp deleted later
   ```

2. When the amount of data read is unknown.

   ```
   vector<int> input;
   int temp;
   for ( ;; ) {
     cin >> temp;
     if ( cin.fail() ) break;
     input.push_back( temp ); // implicit dynamic allocation
   }
   ```

3. When an array of objects must be initialized via the object’s constructor.

   ```
   struct Obj {
     int id; ...
     Obj( int id ) : id( id ) { ...
   }
   cin >> size;
   Obj * objs[size];
   for ( int id = 0; id < size; id += 1 )
     objs[id] = new Obj( id ); // each element has different value
   ...
   for ( int id = 0; id < size; id += 1 )
     delete objs[id];
   ```

   or

   ```
   #include <memory>
   {
     unique_ptr<Obj> objs[size];
     for ( int id = 0; id < size; id += 1 )
       // objs[id].reset( new Obj( id ) ); // C++11
       objs[id] = make_unique<Obj>( id ); // C++14
   }
   // automatically delete objs
   ```

   Alternatives are static variables or initialization after creation (⇒ no constructor).

4. When large local variables are allocated on a small stack.
1.2. DYNAMIC MEMORY ALLOCATION

```c
_Coroutine C {
    void main() {
        // 64K stack
        int arr[100000];  // overflow
        ...
    }
};

_Coroutine C {
    void main() {
        int * arr = new int[100000];
        ...
    }
};
```

Alternatives are large stacks (waste virtual space) or dynamic stack growth (complex and pauses).
2 Dynamic Multi-Level Exit

- Routine **activation** (call/invocation) introduces complex control flow.

- *Among* routines, control flow is controlled by call/return mechanism.
  - routine $h$ calls $g$ calls $f$
  - cannot return from $f$ to $h$, terminating $g$'s activation

- **Modularization**: any contiguous code block can be factored into a (helper) routine and called from anywhere in the program (modulo scoping rules).

- Modularization fails when factoring exits, e.g., multi-level exits:
  
  ```
  B1: for ( i = 0; i < 10; i += 1 ) {
      ...
      B2: for ( j = 0; j < 10; j += 1 ) {
          ...
          if ( ... ) break B1;
          ...
      }
      ...
  }
  ```

  ```
  B2: for ( j = 0; j < 10; j += 1 ) {
      ...
      if ( ... ) break B1;
      ...
  }
  ```

  ```
  int rtn( ... ) {
      B1: for ( i = 0; i < 10; i += 1 ) {
          ...
          w = rtn( ... )
          ...
      }
  }
  ```

- **Fails to compile because labels only have routine scope.**

- Pattern: many routines have **multiple outcomes**.
  - normal: return normal result and transfer after call
  - exceptional: return alternative result and **not** transfer after call
Two alternate return parameters, denoted by * and implicitly named 1 and 2

```
subroutine AltRet( c, *, * )
    integer c
    if ( c == 0 ) return  ! normal return
    if ( c == 1 ) return 1  ! alternate return
    if ( c == 2 ) return 2  ! alternate return
end
```

Statements labelled 10 and 20 are alternate return points

```
call AltRet( 0, *10, *20 )
print *, "normal return 1"
call AltRet( 1, *10, *20 )
print *, "normal return 2"
return
10 print *, "alternate return 1"
call AltRet( 2, *10, *20 )
print *, "normal return 3"
return
20 print *, "alternate return 2"
stop
end
```

```
$ gfortran AltRtn.f90
$ a.out
normal return 1
alternate return 1
alternate return 2
```

- Generalization of multi-exit loop and multi-level exit.
  - Control structures ends normally or with an exceptional transfer.

- Pattern acknowledges:
  - algorithms can have multiple outcomes
  - separating outcomes makes it easy to read and maintain a program

- Pattern does not handle multiple levels of nested modularization.

- if AltRet is further modularized, new routine has an alternate return to AltRet, which retains its alternate return to its caller.
Two alternate return parameters, denoted by * and implicitly named 1 and 2

**subroutine** AltRet2( c, *, * )

```c
integer c
if ( c == 0 ) _return_! normal return
if ( c == 1 ) _return_ 1 ! alternate return
return 2
end
```

Two alternate return parameters, denoted by * and implicitly named 1 and 2

**subroutine** AltRet( c, *, * )

```c
integer c
call AltRet2( c, *30, *40 )
return
30 _return_ 1
40 if ( c == 2 ) return 2 ! alternate return
end
```

• Rather than two step operation, simpler for new modularized routine to bypass intermediate step and transfer directly to caller of AltRet.

• Why not call AltRet2( c, *10, *20 )?

• Dynamic multi-level exit extend call/return semantics to transfer in the reverse direction to normal routine calls, called nonlocal transfer.

```c
label L;
void f( int i ) {
   // nonlocal return
   if ( i == . . . ) _goto_ L;
}
void g( int i ) {
   if ( i > 1 ) { g( i - 1 ); _return_; }
   f( i );
}
void h( int i ) {
   if ( i > 1 ) { h( i - 1 ); _return_; }
   L = L1; // set dynamic transfer–point
   f( 1 ); _goto_ S1;
L1: // handle L1 nonlocal return
S1: // continue normal execution
   L = L2; // set dynamic transfer–point
   g( 1 ); _goto_ S2;
L2: // handle L2 nonlocal return
S2: // continue normal execution
}
```

• Nonlocal transfer mechanism is a label variable containing the tuple:

  1. pointer to a block activation on the stack
  2. transfer point within the block.

• Nonlocal transfer, _goto_ L, in f is a two-step operation:
1. direct control flow to the specified activation on the stack; 
2. then go to the transfer point (label constant) within the routine.

• Therefore, a label value is not statically/lexically determined.
  ○ recursion in g ⇒ unknown distance between f and h on stack.
  ○ what if L is set during the recursion of h?

• This complexity is why label constants have local scope.

• Transfer between goto and label value causes termination of stack block.

• First, nonlocal transfer from f transfers to the label L1 in h’s routine activation, terminating f’s activation.

• Second, nonlocal transfer from f transfers to the static label L2 in the stack frame for h, terminating the stack frame for f and g.

• Termination is implicit for direct transferring to h or requires stack unwinding if activations contain objects with destructors or finalizers.

• Nonlocal transfer is possible in C using:
  ○ jmp_buf to declare a label variable,
  ○ setjmp to initialize a label variable,
  ○ longjmp to goto a label variable.

• Nonlocal transfer allows multiple forms of returns to any level.
  ○ Normal return transfers to statement after the call, often implying completion of routine’s algorithm.
  ○ Exceptional return transfers to statement not after the call, indicating an ancillary completion (but not necessarily an error).

• Unfortunately, nonlocal transfer is too general, allowing branching to almost anywhere, i.e., the goto problem.

2.1 Implementation

• Nonlocal transfer is limited in most programming languages using exception handling.
2.2. TRADITIONAL APPROACHES

- To implement throw/catch, the throw must know the last guarded block with a handler for the raised exception type.

- One approach is to:
  - associate a label variable with each exception type
  - set label variable on entry to each guarded block with handler for the type
  - reset label variable on exit to previous value, i.e., previous guarded block for that type

- For C++, a direct transfer is often impossible because
  - activations on the stack may contain objects with destructors or finalizers
  - hence, linear stack unwinding is necessary.

2.2 Traditional Approaches

- return code: returns value indicating normal or exceptional execution.
  - e.g., printf() returns number of bytes transmitted or negative value.

- status flag: set shared (global) variable indicating normal or exceptional execution; the value remains as long as it is not overwritten.
  - e.g., errno variable in UNIX.

- fix-up routine: a global and/or local routine called for an exceptional event to fix-up and return a corrective result so a computation can continue.
  - e.g., C++ has global routine-pointer new_handler called when new fails.
• Techniques are often combined, e.g.:

```c
if ( printf(...) < 0 ) {
    perror( "printf:" );
    abort();
}
```

• Intermediate approach of `return union`, which mimics normal return type.

• Return union combines result/return-code, and checks code on result access.

• ALL routines must return an appropriate union.

```c
optional< int * > Malloc( size_t size ) {
    if ( random() % 2 ) return (int*)malloc( sizeof( int ) );
    return nullopt;
}
```

```c
optional< int > rtn( ) {
    optional< int * > p = Malloc( sizeof( int ) );
    if ( p ) {
        **p = 7; // compute
        if ( random() % 2 ) return **p;
        return nullopt;
    }
    return nullopt;
}
```

```c
int main() {
    srandrandom( getpid() );
    optional< int > ret = rtn();
    if ( ret ) cout << *ret << endl;
    else cout << "no storage or bad computation" << endl;
}
```

```c
enum Alloc { NoStorage };
variant< int *, Alloc > Malloc( size_t size ) {
    if ( random() % 2 ) return { (int*)malloc( sizeof( int ) ) };
    return { NoStorage };
}
```

```c
enum Comp { Bad };
variant< int, Alloc, Comp > rtn( ) {
    variant< int *, Alloc > p = Malloc( sizeof( int ) );
    if ( holds_alternative<int*>(p) ) {
        *get<int*>(p) = 7;
        if ( random() % 2 ) return { *get<int*>(p) };
        return { Bad };
    }
    return { NoStorage };
}
```
2.2. TRADITIONAL APPROACHES

```c
int main() {
    srandom( getpid() );
    variant< int, Alloc, Comp > ret = rtn();
    if ( holds_alternative<int>(ret) ) cout << get<int>(ret) << endl;
    else if ( holds_alternative<Comp>(ret) ) cout << "bad computation" << endl;
    else cout << "no storage" << endl;
}
```

$ repeat 5 a.out
no storage
bad computation
no storage
bad computation
7

- Mostly forces checking, but can still ignore, access without holds_alternative check

- Like Fortran, both only return one level.

- Drawbacks of traditional techniques:
  - checking return code or status flag is optional ⇒ can be delayed or omitted, i.e., passive versus active
  - return code mixes exceptional and normal values ⇒ enlarges type or value range; normal/exceptional type/values should be independent

- Testing and handling of return code or status flag is often done locally (inline), otherwise information may be lost; but local testing/handling:
  - makes code difficult to read; each call results in multiple statements
  - can be inappropriate; library routines should not terminate program

- Nonlocal (non-inline) return code or status flag testing is difficult because multiple values must be returned to higher-level code for subsequent analysis, compounding the mixing problem.

- Status flag can be overwritten before examined, and cannot be used in a concurrent environment because of sharing issues (e.g., save error)

- Local fix-up routines increases the number of parameters:
  - increase cost of each call
  - must be passed through multiple levels enlarging parameter lists even when the fix-up routine is not used

- Nonlocal (global) fix-up routines, implemented with global routine pointer, have identical problems with status flags (e.g., new_handler).
Simulate dynamic multi-level exit with return codes.

```c
label L;
void f( int i, int j ) {
    for ( ... ) {
        int k;
        ...
        if ( i < j && k > i ) goto L;
        ...
    }
}

void g( int i ) {
    for ( ... ) {
        int j;
        ... f( i, j ); ...
    }
}

void h() {
    L = L1;
    for ( ... ) {
        int i;
        ... g( i ); ...
    }
    ... return; // normal  
    L1: ... // exceptional
}
```

```c
int f( int i, int j ) {
    bool flag = false;
    for ( ! flag && ... ) {
        int k;
        ...
        if ( i < j && k > i ) flag = true;
        else { ... }
    }
    if ( ! flag ) { ... }
    return flag ? -1 : 0;
}

int g( int i ) {
    bool flag = false;
    for ( ! flag && ... ) {
        int j;
        ... f( i, j ); ...
        if ( f( i, j ) == -1 ) flag = true
        else { ... }
    }
    if ( ! flag ) { ... }
    return flag ? -1 : 0;
}

void h() {
    bool flag = false;
    for ( ! flag && ... ) {
        int i;
        ... g( i ); ...
        if ( g( i ) == -1 ) flag = true;
        else { ... }
    }
    if ( ! flag ) { ... return; }
    ... 
}
```

2.3 Exception Handling

- Dynamic multi-level exit allows complex forms of transfers among routines.
- Complex control-flow among routines is often called exception handling.
- Exception handling is more than error handling.
- An exceptional event is an event that is (usually) known to exist but which is ancillary to an algorithm.
  - an exceptional event usually occurs with low frequency
  - e.g., division by zero, I/O failure, end of file, pop empty stack
- An exception handling mechanism (EHM) provides some or all of the alternate kinds of control-flow.
• Very difficult to simulate EHM with simpler control structures.

• Exceptions are supposed to make certain programming tasks easier, like robust programs.

• Robustness results because exceptions are active versus passive, forcing programs to react immediately when an exceptional event occurs.

• An EHM is not a panacea and only as good as the programmer using it.

2.4 Execution Environment

• The execution environment has a significant effect on an EHM.

• An object-oriented concurrent environment requires a more complex EHM than a non-object-oriented sequential environment.

• E.g., objects may have destructors that must be executed no matter how the object ends, i.e., by normal or exceptional termination.

```java
class T {
  int *i;
  T() { i = new int[10]; ... }
  ~T() { delete [] i; ... } // must free storage
};
L: {
  T t; // constructor must be executed
  ... if ( ... ) break L;
  ...
} // destructor must be executed
```

• Control structures with `finally` clauses must always be executed (e.g., Java/μC++)

<table>
<thead>
<tr>
<th>Java</th>
<th>μC++</th>
</tr>
</thead>
</table>
| L: try {
  infile = new Scanner( new File( "abc" ) );
  ... if ( ... ) break L;
  ... } finally { // always executed
    infile.close(); // must close file
}                                      | L: try {
  infile = new ifstream( "abc" );
  ... if ( ... ) break L; // alt 1
  ... // alt 2
} _Finally { // always executed
  infile.close(); // must close file
  delete infile; // deallocate
}                                      |

• Hence, terminating a block complicates the EHM as object destructors (and recursively for nested objects) and `finally` clauses must be executed.

• Also, complex execution-environment involving continuation, coroutine, task, each with its own execution stack.

• Given multiple stacks, an EHM can be more sophisticated, resulting in more complexity.
  
  o e.g., if no handler is found in one stack, it is possible to continue propagating the exception in another stack.
2.5 Terminology

- **execution** is the language unit in which an exception can be raised, usually any entity with its own runtime stack.

- **exception type** is a type name representing an exceptional event.

- **exception** is an instance of an exception type, generated by executing an operation indicating an ancillary (exceptional) situation in execution.

- **raise (throw)** is the special operation that creates an exception.

- **source execution** is the execution raising an exception.

- **faulting execution** is the execution changing control flow due to a raised exception.

- **local exception** is when an exception is raised and handled by the same execution \( \Rightarrow \) source \( = \) faulting.

- **nonlocal exception** is when an exception is raised by a source execution but **delivered** to a different faulting execution \( \Rightarrow \) source \( \neq \) faulting.

- **concurrent exception** is a nonlocal exception, where the source and faulting executions are executing concurrently.

- **propagation** directs control from a raise in the source execution to a handler in the faulting execution.

- **propagation mechanism** is the rules used to locate a handler.
  - most common propagation-mechanisms give precedence to handlers higher in the lexical/call stack
    - specificity versus generality
    - efficient linear search during propagation

- **handler** is inline (nested) routine responsible for handling raised exception.
  - handler **catches** exception by **matching** with one or more exception types
  - after catching, a handler executes like a normal subroutine
  - handler can return, reraise the current exception, or raise a new exception
  - **reraise** terminate current handling and continuing propagation of caught exception.
    - useful if a handler cannot deal with an exception but needs to propagate same exception to handler further down the stack.
    - provided by a raise statement without an exception type:
      ```
      . . . throw;  // no exception type
      where a raise must be in progress.
      ```
  - an exception is **handled** only if the handler returns rather than reraises
• **guarded block** is a language block with associated handlers, e.g., try-block in C++/Java.

• **unguarded block** is a block with no handlers.

• **termination** means control cannot return to the raise point.
  
  ○ all blocks on the faulting stack from the raise block to the guarded block handling the exception are terminated, called **stack unwinding**

• **resumptions** means control returns to the raise point ⇒ no stack unwinding.

• EHM = Exception Type + Raise (exception) + Propagation + Handlers

### 2.6 Static/Dynamic Call/Return

• All routine/exceptional control-flow can be characterized by two properties:

  1. **static/dynamic call**: routine/exception name at the call/raise is looked up statically (compile-time) or dynamically (runtime).

  2. **static/dynamic return**: after a routine/handler completes, it returns to its static (definition) or dynamic (call) context.

<table>
<thead>
<tr>
<th>return/handled</th>
<th>call/raise</th>
</tr>
</thead>
<tbody>
<tr>
<td>static</td>
<td>static</td>
</tr>
<tr>
<td></td>
<td>1) sequel</td>
</tr>
<tr>
<td>dynamic</td>
<td>dynamic</td>
</tr>
<tr>
<td></td>
<td>2) routine</td>
</tr>
<tr>
<td></td>
<td>3) termination exception</td>
</tr>
<tr>
<td></td>
<td>4) routine pointer, virtual routine, resumption</td>
</tr>
</tbody>
</table>

• E.g., case 2) is a normal routine, with static name lookup at the call and a dynamic return.

### 2.7 Static Propagation (Sequel)

• Case 1) is called a **sequel**, which is a routine with no return value, where:
  
  ○ the sequel name is looked up lexically at the call site, but

  ○ control returns to the end of the block in which the sequel is declared.
• Without a sequel, it is impossible to modularize code with static exits.

• ⇒ propagation is along the lexical structure

• Adheres to the termination model, as the stack is unwound.

• Sequel handles termination for a non-recoverable event (simple exception handling).

• The advantage of the sequel is the handler is statically known (like static multi-level exit), and can be as efficient as a direct transfer.

• The disadvantage is that the sequel only works for monolithic programs because it must be statically nested at the point of use.

  ◦ Fails for modular (library) code as the static context of the module and user code are disjoint.

  ◦ E.g., if stack is separately compiled, the sequel call in push no longer knows the static blocks containing calls to it.
2.8 Dynamic Propagation

- Cases 3) and 4) are called termination and resumption, and both have dynamic raise with static/dynamic return, respectively.

- Dynamic propagation/static return (case 3) is also called dynamic multi-level exit (see Section 2, p. 7).

- The advantage is that dynamic propagation works for separately-compiled programs.

- The disadvantage (advantage) of dynamic propagation is the handler is not statically known.
  - without dynamic handler selection, the same action and context for that action is executed for every exceptional change in control flow.

2.8.1 Termination

- For termination:
  - control transfers from the start of propagation to a handler $\Rightarrow$ dynamic raise (call)
  - when handler returns, it performs a static return $\Rightarrow$ stack is unwound (like sequel)

- There are 3 basic termination forms for a non-recoverable operation: nonlocal, terminate, and retry.

- Nonlocal transfer provides general mechanism for block transfer on call stack, but has goto problem (see Section 2, p. 7).

- terminate provides limited mechanism for block transfer on the call stack, like labelled break (see return union examples page 12):

```c
struct Alloc {};  
struct Comp {};  
int * Malloc( size_t size ) {  
    if ( random() % 2 ) return (int *)malloc( sizeof( int ) );  
    throw Alloc{};  
}  
int rtn( ) {  
    int * p = Malloc( sizeof( int ) );  
    *p = 7;  // compute  
    if ( random() % 2 ) return *p;  
    throw Comp{};  
}  

int main() {  
    srand( getpid() );  
    try { cout << rtn() << endl; }  
    catch( Comp ) { cout << "bad computation" << endl; }  
    catch( Alloc ) { cout << "no storage" << endl; }  
}  
```
• C++ I/O can be toggled to raise exceptions versus return codes (like \( \mu \)C++).

<table>
<thead>
<tr>
<th>C++</th>
<th>( \mu )C++</th>
</tr>
</thead>
<tbody>
<tr>
<td>ifstream infile; ofstream outfile; outfile.exceptions( ios_base::failbit ); infile.exceptions( ios_base::failbit );</td>
<td>ifstream infile; ofstream outfile;</td>
</tr>
<tr>
<td>switch ( argc ) { case 3: try { outfile.open( argv[2] ); } catch( ios_base::failure ) {...} // fall through to handle input file case 2: try { infile.open( argv[1] ); } catch( ios_base::failure ) {...} break; default: ... } // switch string line; try { for ( ;; ) { // loop until end-of-file getline( infile, line ); outfile &lt;&lt; line &lt;&lt; endl; } } catch( ios_base::failure ) {}</td>
<td>switch ( argc ) { case 3: try { outfile.open( argv[2] ); } catch( uFile::Failure &amp; ) {...} // fall through to handle input file case 2: try { infile.open( argv[1] ); } catch( uFile::Failure &amp; ) {...} break; default: ... } // switch string line; for ( ;; ) { getline( infile, line ); if ( infile.fail() ) break; // no eof exception outfile &lt;&lt; line &lt;&lt; endl; }</td>
</tr>
</tbody>
</table>

• An exception handler can generated an arbitrary number of nested exceptions.

```cpp
struct E {}; int cnt = 3; void f( int i ) { if ( i == 0 ) throw E(); try { f( i - 1 ); } catch( E ) { // handler h cnt -= 1; if ( cnt > 0 ) f( 2 ); } h throw E1 f } int main() { f( 2 ); }
```

• Exceptions are nested as handler can rethrow its matched exception when control returned.
2.8. DYNAMIC PROPAGATION

- **retry** is a combination of termination with special handler semantics, i.e., restart the guarded block handling the exception (Eiffel). (Pretend end-of-file is an exception of type Eof.)

<table>
<thead>
<tr>
<th>Retry</th>
<th>Simulation</th>
</tr>
</thead>
</table>
| char readfiles( char *files[], int N ) {  
  int i = 0, value;  
  ifstream infile;  
  infile.open( files[i] );  
  try  
  {  
    . . . infile >> value; . . .  
  }  
  retry( Eof ) {  
    i += 1;  
    infile.close();  
    if ( i == N ) goto Finished;  
    infile.open( files[i] );  
  }  
  Finished: ;  
} | char readfiles( char *files[], int N ) {  
  int i = 0, value;  
  ifstream infile;  
  infile.open( files[i] );  
  while ( true ) {  
    try {  
      . . . infile >> value; . . .  
    }  
    catch( eof ) {  
      i += 1;  
      infile.close();  
      if ( i == N ) break;  
      infile.open( files[i] );  
    }  
  } |

- Because retry can be simulated, it is seldom supported directly.

- However, setting/resetting label variable on **try** block entry/exit is expensive:
  - rtn called million times but exception E never raised ⇒ million unnecessary operations.
  - void rtn( int i ) {  
      try {  
        . . .  
      }  
      catch( E ) { . . . }  
    }  
  
  - Instead, catch/destructor data is stored once externally for each block and handler found by linear search during a stack walk (no direct transfer).
  - Advantage, millions of **try** entry/exit, but only tens of exceptions raised.

- Hence, termination are often implemented using zero cost on guarded-block entry but an expensive approach on raise.

2.8.2 Resumption

- **resumption** provides a *limited* mechanism to generate new blocks on the call stack:
  - control transfers from the start of propagation to a handler ⇒ dynamic raise (call)
  - when handler returns, it is dynamic return ⇒ stack is NOT unwound (like routine)

- A resumption handler is a corrective action so a computation can continue.
void f() {
    resume E(); // raise
    // control returns here
}

int main() {
    try {
        f(); // no parameters
        catch( E ) {
            // handler 1
        }
    }
    catch( E ) {
        // handler 2
    }
}

void f( void (*fixup)() ) {
    fixup();
    // control returns here
}

void fixup1() {
    // handler 1
}

void fixup2() {
    // handler 2
}

int main() {
    f( fixup1 ); // parameters
    f( fixup2 ); // parameters
}

2.9 Exceptional Example

B1 {
    try {
        try {
            try {
                try {
                    ... throw E5(); ...
                    catch( E7 ) { ... }
                } catch( E5 ) { ... throw; ... }
                catch( E6 ) { ... }
                catch( E3 ) { ... }
            } catch( E5 ) { ... resume/retry/terminate }
            catch( E2 ) { ... }
        }
    }
}
2.10  \( \mu \text{C++ EHM} \)

The following features characterize the \( \mu \text{C++ EHM} \):

- exceptions must be generated from a specific kind of type.
- supports two forms of raising: throw and resuming.
- supports two kinds of handlers, termination and resumption, which match with the kind of raise.
- supports propagation of nonlocal and concurrent exceptions.
- all exception types (user, runtime, and I/O) are grouped into a hierarchy.

2.11  \( \mu \text{C++ EHM} \)

- \( \text{C++} \) allows any type to be used as an exception type.
- \( \mu \text{C++} \) restricts exception types to those types defined by \_Event.

    \_Event exception-type-name {
    
    };

- An exception type has all the properties of a \textbf{class}.
- Every exception type must have a public default and copy constructor.
• An exception is the same as a class-object with respect to creation and destruction:

```c++
_Event D { ... }
D d; // local creation
_Resume d;
D *dp = new D; // dynamic creation
_Resume *dp;
delete dp;
_Throw D(); // temporary local creation
```

2.12 Inherited Members

• Each exception type inherits the following members from uBaseEvent:

```c++
class uBaseEvent {
    uBaseEvent( const char *const msg = "" );
    const char *const message() const;
    const uBaseCoroutine &source() const;
    const char *sourceName() const;
    virtual void defaultTerminate();
    virtual void defaultResume();
};
```

• uBaseEvent( const char *const msg = "" ) – msg is printed if the exception is not caught. msg is copied so it is safe to use within an exception even if the context of the raise is deleted.

• message returns the string message associated with an exception.

• source returns the coroutine/task that raised the exception.
  coroutine/task may be deleted when the exception is caught so this reference may be undefined.

• sourceName returns the name of the coroutine/task that raised the exception.
  name is copied from the raising coroutine/task when exception is created.

• defaultTerminate is implicitly called if an exception is thrown but not handled.
  default action is to terminate the program with the supplied message.

• defaultResume is implicitly called if an exception is resumed but not handled.
  default action is to throw the exception.

2.13 Raising

• There are two raising mechanisms: throwing and resuming.

```c++
_Throw [ exception-type ]
_Resume [ exception-type ] [ _At uBaseCoroutine-id ]
```
• If _Throw has no exception-type, it is a rethrow.

• If _Resume has no exception-type, it is a reresume.

• The optional _At clause allows the specified exception or the currently propagating exception to be raised at another coroutine or task.

• Nonlocal/concurrent raise restricted to resumption as raising execution-state is often unaware of the handling execution-state.

• Resumption allows faulting execution greatest flexibility: it can process the exception as a resumption or rethrow the exception for termination.

• Exceptions in µC++ are propagated differently from C++.

<table>
<thead>
<tr>
<th>C++</th>
<th>µC++</th>
</tr>
</thead>
<tbody>
<tr>
<td>class B {}; class D : public B {}; void f( B &amp; t ) { throw t; } D m; f( m );</td>
<td>_Event B {}; _Event D : public B {}; _Throw t; D m; f( m );</td>
</tr>
</tbody>
</table>

○ In C++, routine f is passed an object of derived type D but throws an object of base type B.

○ In µC++, routine f is passed an object of derived type D and throws the original object of type D.

○ This change allows handlers to catch the specific (derived) rather than the general (base) exception-type.

• Notice, catching truncation (see page 57) is different from raising truncation, which does not occur in µC++.

2.14 Handler

• µC++ has two kinds of handlers, termination and resumption, which match with the kind of raise.

2.14.1 Termination

• The µC++ termination handler is the catch clause of a try block, i.e., same as in C++.
2.14.2 Resumption

- A resumption handler is often a corrective action for a failing operation.

- Unlike normal routine calls, the call to a resumption handler is dynamically bound rather than statically bound.

- \( \mu \text{C++} \) extends the try block to include resumption handlers.

- Resumption handler is denoted by a _CatchResume clause at the end of a try block:

  ```
  try {
    ...
  } _CatchResume( E1 ) { ... } // must appear before catch clauses
  // more _CatchResume clauses
  _CatchResume( ... ) { ... } // must be last _CatchResume clause
  catch( E2 ) { ... } // must appear after _CatchResume clauses
  // more catch clauses
  catch( ... ) { ... } // must be last catch clause
  ```

- Any number of resumption handlers can be associated with a try block.

- All _CatchResume handlers must precede any catch handlers.

- Like catch(…) (catch-any), _CatchResume(…) must appear at the end of the list of the resumption handlers.

- Resumption handler can access types and variables visible in its local scope.

  ```
  typedef int Foo;
  Foo i;
  try {
    f(…) // f is recursive and raises Foo
  } _CatchResume( Foo & e ) { // handler H
    Foo fix = i; // use type and variable in local scope
    ... e = fix ... // change _Resume block
  }
  ```

- **lexical link** is like this but to declaration block rather than object.

- **Resumption handler cannot perform a break, continue or return.**
  - Resumption handler is corrective action so computation can continue.
If correction impossible, handler should throw an exception not step into an enclosing block to cause the stack to unwind.

```
B: try {
    f(); // recursive calls and _Resume E()
} _CatchResume( E e ) { // handler H
    ... break B; // force static return (disallowed)
    _Throw e; // force recover (allowed)
}
```

- Handler H above recursive calls to f, so `goto` must unwind stack to transfer into stack frame B (nonlocal transfer).
- Throw may find another recovery action closer to raise point than B that can deal with the problem.
- Cannot rethrow because propagation is currently resumption ⇒ must start throw propagation.

### 2.14.3 Termination/Resumption

- The raise dictates set of handlers examined during propagation:
  - terminating propagation (_Throw) only examines termination handlers (`catch`),
  - resuming propagation (_Resume) only examines resumption handlers (_CatchResume).
- Exception types in each set can overlap:

```
_Event E {};
void rtn() {
    try {
        _Resume E();
    } _CatchResume( E e ) { ... _Throw e; } // H1
    catch( E e ) { ... } // H2
}
```

- Resumption handler H1 is invoked by the resume in the `try` block generating call stack:
  - `rtn` → `try[ ] _CatchResume( E ), catch( E )` → H1
- Handler H1 throws E and the stack is unwound until the exception is caught by termination-handler `catch( E )` and handler H2 is invoked.
  - `rtn` → H2
- The termination handler is available as resuming does not unwind the stack.
- Note interaction between resuming, defaultResume, and throwing:

```
_Event R {};
void rtn() {
    try {
        _Resume R(); // resume not throw
    } catch( R ) { ... } // H1, no _CatchResume!!!
}
```
• This generates the following call stack as there is no eligible resumption handler (or there is
a handler but marked ineligible):

\[
\text{rtn} \rightarrow \text{try[} \text{catch( R )} \rightarrow \text{defaultResume}
\]

• *When defaultResume is called, the default action throws R* (see Section 2.12, p. 24).

\[
\text{rtn} \rightarrow \text{H1}
\]

• Terminating propagation unwinds the stack until there is a match with the *catch* clause in the *try* block.
3 Coroutine

- A **coroutine** is a routine that can also be suspended at some point and resumed from that point when control returns.

- The state of a coroutine consists of:
  
  - an **execution location**, starting at the beginning of the coroutine and remembered at each suspend.
  
  - an **execution state** holding the data created by the code the coroutine is executing.

  ⇒ each coroutine has its own stack, containing its local variables and those of any routines it calls.

  - an **execution status**—**active** or **inactive** or **terminated**—which changes as control resumes and suspends in a coroutine.

- Hence, a coroutine does not start from the beginning on each activation; it is activated at the point of last suspension.

- In contrast, a routine always starts execution at the beginning and its local variables only persist for a single activation.

- A coroutine handles the class of problems that need to retain state between calls (e.g. plugin, device driver, finite-state machine).

- A coroutine executes synchronously with other coroutines; hence, no concurrency among coroutines.

- Coroutines are the precursor to concurrent tasks, and introduce the complex concept of suspending and resuming on separate stacks.

- Two different approaches are possible for activating another coroutine:

  1. A **semi-coroutine** acts asymmetrically, like non-recursive routines, by implicitly reactivating the coroutine that previously activated it.
2. A **full-coroutine** acts symmetrically, like recursive routines, by explicitly activating a member of another coroutine, which directly or indirectly reactivates the original coroutine (activation cycle).

- These approaches accommodate two different styles of coroutine usage.

### 3.1 Semi-Coroutine

#### 3.1.1 Fibonacci Sequence

\[
f(n) = \begin{cases} 
0 & n = 0 \\
1 & n = 1 \\
f(n-1) + f(n-2) & n \geq 2 
\end{cases}
\]

- 3 states, producing unbounded sequence: 0, 1, 1, 2, 3, 5, 8, 13, 21, …

#### 3.1.1.1 Direct

- Compute and print Fibonacci numbers.

```c
int main() {
    int fn, fn1, fn2;
    fn = 0; fn1 = fn; // 1st case
    cout << fn << endl;
    fn = 1; fn2 = fn1; fn1 = fn; // 2nd case
    cout << fn << endl;
    for ( ;; ) { // infinite loop
        fn = fn1 + fn2; fn2 = fn1; fn1 = fn; // general case
        cout << fn << endl;
    }
}
```

- Convert to routine that generates a sequence of Fibonacci numbers on each call (no output):

```c
int main() {
    for ( int i = 1; i <= 10; i += 1 ) { // first 10 Fibonacci numbers
        cout << fibonacci() << endl;
    }
}
```

- Examine different solutions.
3.1. SEMI-COROUTINE

3.1.1.2 Routine

```c
int fn1, fn2, state = 1; // global variables
int fibonacci() {
    int fn;
    switch (state) {
        case 1:
            fn = 0; fn1 = fn; state = 2;
            break;
        case 2:
            fn = 1; fn2 = fn1; fn1 = fn; state = 3;
            break;
        case 3:
            fn = fn1 + fn2; fn2 = fn1; fn1 = fn;
            break;
    }
    return fn;
}
```

- unencapsulated global variables necessary to retain state between calls

- only one fibonacci generator can run at a time

- execution state must be explicitly retained

```c
#define FIB_INIT { 0, 1 } /* first two Fibonacci numbers */
struct Fibonacci { int fn2, fn1; };
int fib( Fibonacci & f ) {
    int ret = f.fn2;
    int fn = f.fn1 + f.fn2;
    f.fn2 = f.fn1; f.fn1 = fn;
    return ret;
}
int main() {
    Fibonacci f1 = FIB_INIT, f2 = FIB_INIT; // multiple instances
    for ( int i = 1; i <= 10; i += 1 ) {
        cout << fib( f1 ) << " " << fib( f2 ) << endl;
    } // for
}
```

- unencapsulated program global variables become encapsulated structure variables

- multiple fibonacci generators (objects) can run at a time

- execution state removed by precomputing first 2 Fibonacci numbers and returning $f(n - 2)$
3.1.1.3 Class

```cpp
class Fibonacci {
    int fn, fn1, fn2, state = 1; // global class variables

public:
    int operator()() {  // functor
        switch (state) {
            case 1:
                fn = 0; fn1 = fn; state = 2;
                break;
            case 2:
                fn = 1; fn2 = fn1; fn1 = fn; state = 3;
                break;
            case 3:
                fn = fn1 + fn2; fn2 = fn1; fn1 = fn;
                break;
        }
        return fn;
    }
};

int main() {
    Fibonacci f1, f2; // multiple instances
    for (int i = 1; i <= 10; i += 1) {
        cout << f1() << " " << f2() << endl;
    } // for
}
```

• unencapsulated program global variables become encapsulated object global variables
• multiple fibonacci generators (objects) can run at a time
• execution state still explicit or use initialization trick

3.1.1.4 Coroutine

```cpp
Coroutine Fibonacci { // : public uBaseCoroutine
    int fn; // used for communication

public:
    int operator()() {  // functor
        resume(); // transfer to last suspend
        return fn;
    }
};
```
3.1. SEMI-COROUTINE

```cpp
int main() {
    Fibonacci f1, f2;  // multiple instances
    for ( int i = 1; i <= 10; i += 1 ) {
        cout << f1() << " " << f2() << endl;
    }
}
```

- **no explicit execution state!** (see direct solution)
- **Coroutine** type wraps coroutine and provides *all class* properties
  - distinguished member `main` (coroutine main) can be suspended and resumed
  - no parameters or return value (supplied by *public* members and communication variables).
  - coroutine `main` can be called (even recursively), but normally a *private/protected* member. Why?
- **compile with u++ command**
- All coroutines inherit from base type `uBaseCoroutine`:
  ```cpp
  _Coroutine uBaseCoroutine {
  protected:
      void resume();  // context switch to this
      void suspend(); // context switch to last resumer
  public:
      uBaseCoroutine();
      uBaseCoroutine( unsigned int stackSize ); // set stack size
      void verify();      // check stack
      const char * setName( const char * name ); // printed in error messages
      const char * getName() const;
      uBaseCoroutine & starter() const; // coroutine performing first resume
      uBaseCoroutine & resumer() const; // coroutine performing last resume
  }
  ```
- Program main called from hidden coroutine ⇒ has coroutine properties.
- resume/suspend cause a **context switch** between coroutine stacks

![Diagram](https://via.placeholder.com/150)

- first resume starts main on new stack (cocall); subsequent resumes reactivate last suspend.
- suspend reactivates last resume.
• object becomes a coroutine on first resume; coroutine becomes an object when main ends

• routine frame at the top of the stack knows where to activate execution

• suspend/resume are protected members to prevent external calls. Why?

• Coroutine main does not have to return before a coroutine object is deleted.

• When deleted, a coroutine’s stack is always unwound and any destructors executed. Why?

3.1.2 Format Output

Unstructured input:

defghijklmnopqrstuvwxyzabcdefghijklmnopqrstuvwxyz

Structured output:

abcd efgh i j k l m nop qr st uv w xyz ab c de fg hi j k l m nop qr st uv w xyz

blocks of 4 letters, separated by 2 spaces, grouped into lines of 5 blocks.

3.1.2.1 Direct

• Read characters and print formatted output.

```cpp
int main() {
    int g, b;
    char ch;
    cin >> noskipws;       // turn off white space skipping
    for ( ;; ) {          // for as many characters
        for ( g = 0; g < 5; g += 1 ) { // groups of 5 blocks
            for ( b = 0; b < 4; b += 1 ) { // blocks of 4 chars
                for ( ;; ) {      // for newline characters
                    cin >> ch;     // read one character
                    if ( cin.fail() ) goto fini; // eof? multi-level exit
                    if ( ch != '\n' ) break; // ignore newline
                }
                cout << ch;       // print character
            }
            cout << ' ';      // print block separator
        }
        cout << endl;     // print group separator
    }
    fini: ;
    if ( g != 0 || b != 0 ) cout << endl; // special case
}
```

• Convert to routine passed one character at a time to generate structured output (no input).
3.1.2.2 Routine

```c++
int g, b; // global variables

void fmtLines(char ch) {
    if (ch != -1) { // not EOF?
        if (ch == '\n') return; // ignore newline
        cout << ch; // print character
        b += 1;
        if (b == 4) { // block of 4 chars
            cout << " "; // block separator
            b = 0;
            g += 1;
        }
        if (g == 5) { // group of 5 blocks
            cout << endl; // group separator
            g = 0;
        }
    } else {
        if (g != 0 || b != 0) cout << endl; // special case
    }
}

int main() {
    char ch;
    cin >> noskipws; // turn off white space skipping
    for (;;) {
        cin >> ch;
        if (cin.fail()) break; // eof?
        fmtLines(ch);
    }
    fmtLines(-1); // indicate EOF
}
```

- must retain variables b and g between successive calls.
- only one instance of formatter
- linearize (flatten) loops: one loop, lots of if statements

3.1.2.3 Class

```c++
class Format {
    int g, b; // global class variables

public:
    Format() : g(0), b(0) {}
    ~Format() { if (g != 0 || b != 0) cout << endl; }
    void prt(char ch) {
        if (ch == '\n') return; // ignore newline
        cout << ch; // print character
        b += 1;
    }
}
```
if ( b == 4 ) {
    cout << " ";  // block separator
    b = 0;
    g += 1;
}
if ( g == 5 ) {
    cout << endl;  // group separator
    g = 0;
}

• Solves encapsulation and multiple instances issues, but explicitly managing execution state.

3.1.2.4 Coroutine

Coroutine Format {
    char ch;  // used for communication
    int g, b;  // global because used in destructor
    void main() {
        for ( ;; ) {  // for as many characters
            cin >> noskipws;  // turn off white space skipping
            for ( g = 0; g < 5; g += 1 ) {  // groups of 5 blocks
                for ( b = 0; b < 4; b += 1 ) {  // blocks of 4 characters
                    for ( ;; ) {  // for newline characters
                        suspend();
                        if ( ch != '\n' ) break;  // ignore newline
                    }
                    cout << ch;  // print character
                }
                cout << " ";  // print block separator
            }
            cout << endl;  // print group separator
        }
    }
}
public:
    Format() { resume(); }  // start coroutine
    ~Format() { if ( g != 0 || b != 0 ) cout << endl; }
    void prt( char ch ) { Format::ch = ch; resume(); }
};
3.1. SEMI-COROUTINE

```cpp
int main() {
    Format fmt;
    char ch;
    cin >> noskipws; // turn off white space skipping
    for ( ;; ) {
        cin >> ch; // read one character
        if ( cin.fail() ) break; // eof ?
        fmt.prt( ch );
    }
}
```

- resume in constructor allows coroutine main to get to 1st input suspend.

3.1.3 Correct Coroutine Usage

- Eliminate computation or flag variables retaining information about execution state.

- E.g., sum even and odd digits of 10-digit number, where each digit is passed to coroutine:

<table>
<thead>
<tr>
<th>BAD: Explicit Execution State</th>
<th>GOOD: Implicit Execution State</th>
</tr>
</thead>
</table>
| ```cpp
    for ( int i = 0; i < 10; i += 1 ) {
        if ( i % 2 == 0 ) // even ?
            even += digit;
        else
            odd += digit;
        suspend();
    }
``` | ```cpp
    for ( int i = 0; i < 5; i += 1 ) {
        even += digit;
        suspend();
        odd += digit;
        suspend();
    }
``` |

- Right example illustrates coroutine “Zen”; let it do the work.

- E.g., a BAD solution for the previous Fibonacci generator is:
void main() {
    int fn1, fn2, state = 1;
    for ( ;; ) {
        switch (state) { // no Zen
            case 1:
                fn = 0; fn1 = fn;
                state = 2;
                break;
            case 2:
                fn = 1; fn2 = fn1; fn1 = fn;
                state = 3;
                break;
            case 3:
                fn = fn1 + fn2; fn2 = fn1; fn1 = fn;
                break;
        }
        suspend(); // no Zen
    }
}

• Coroutine’s capabilities not used:
  o explicit flag variable controls execution state
  o original program structure lost in switch statement

• Must do more than just activate coroutine main to demonstrate understanding of retaining data and execution state within a coroutine.

3.1.4 Coroutine Construction
• Fibonacci and formatter coroutines express original algorithm structure (no restructuring).
• When possible, simplest coroutine construction is to write a direct (stand-alone) program.
• Convert to coroutine by:
  o putting processing code into coroutine main,
  o converting reads if program is consuming or writes if program is producing to suspend,
    * Fibonacci consumes nothing and produces (generates) Fibonacci numbers ⇒ convert writes (cout) to suspends.
    * Formatter consumes characters and only indirectly produces output (as side-effect) ⇒ convert reads (cin) to suspends.
  o use interface members and communication variables to transfer data in/out of coroutine.

3.2 Nonlocal Exceptions
• Nonlocal exceptions are exception raised by a source execution at a faulting execution.
• Nonlocal exceptions are possible because each coroutine (execution) has its own stack.
• Nonlocal exceptions are raised using \texttt{_Resume} \ldots \texttt{_At} \ldots.

\begin{verbatim}
(Event E {};
Coroutine C {
  void main() {
    // initialization, no nonlocal delivery
    try {
      // setup handlers
      _Enable {
        // allow nonlocal exceptions
        ... suspend(); ...
      } // disable all nonlocal exceptions
    } catch( E ) {
      // handle nonlocal exception
    }
    // finalization, no nonlocal delivery
  }
}
public:
C() { resume(); } // prime try (not always possible)
void mem() { resume(); }
};
int main() {
  C c;
  _Resume E() _At c; // exception pending
  c.mem(); // trigger exception
}
\end{verbatim}

• For nonlocal resumption, \texttt{_Resume} is a proxy for actual raise in the faulting coroutine $\Rightarrow$ non-local resumption becomes local resumption.

\begin{center}
\begin{tikzpicture}
  \node [draw] (source) at (0,0) {\texttt{main}};
  \node [draw] (faulting) at (3,0) {c};
  \node [draw] (enable) at (1.5,-1) {\texttt{_Enable}};
  \node [draw] (suspend) at (1.5,-2) {suspend};
  \node [draw] (resume) at (1.5,-3) {resume};
  \node [draw] (resume_proxy) at (1.5,-4) {\texttt{_Resume E} \texttt{_At} c};

  \draw [->] (source) -- (enable);
  \draw [->] (enable) -- (suspend);
  \draw [->] (suspend) -- (resume);
  \draw [->] (resume) -- (resume_proxy);
  \draw [->] (resume_proxy) -- (faulting);

  \node at (2,-0.5) {activate};

\end{tikzpicture}
\end{center}

• While source delivers nonlocal exception immediately, propagation only occurs when faulting becomes active.

$\Rightarrow$ must suspend back to or call a member that does a resume of the faulting coroutine

• Faulting coroutine performs local \texttt{_Resume} implicitly at detection points for nonlocal exceptions, e.g., in \texttt{_Enable}, suspend, resume.

• Handler does not return to the proxy raise; control returns to the implicit local raise at exception delivery, e.g., back in \texttt{_Enable}, suspend, resume.

• Multiple nonlocal exceptions are queued and delivered in FIFO order depending on the current enabled exceptions.

• \textbf{Nonlocal delivery is initially disabled for a coroutine}, so handlers can be set up before any exception can be delivered (also see Section 5.11, p. 77).
• Hence, nonlocal exceptions must be explicitly enabled before delivery can occur with _Enable.

• _C++ allows dynamic enabling and disabling of individual exception types versus all exception types.

```cpp
_Enable <E1><E2>... {
    // exceptions E1, E2 are enabled
}
_Disable <E1><E2>... {
    // exceptions E1, E2 are disabled
}
```

• Specifying no exceptions is shorthand for specifying all nonlocal exceptions.

• _Enable and _Disable blocks can be nested, turning delivery on/off on entry and reestablishing the delivery state to its prior value on exit.

• An unhandled exception raised by a coroutine raises a nonlocal exception of type uBaseCoroutine::UnhandledException at the coroutine’s last resumer and then terminates the coroutine.

```cpp
_Event E {};  
_Coroutine C {
    void main() { _Throw E(); }
    public:
        void mem() { resume(); } // continue _CatchResume
};
int main() {
    C c;
    try {
        c.mem();
        _CatchResume( uBaseCoroutine::UnhandledException ) {...}
    } catch( uBaseCoroutine::UnhandledException ) {...}
    // continue catch
}
```

• Call to c.mem resumes coroutine c and then coroutine c throws exception E but does not handle it.

• When the base of c’s stack is reached, an exception of type uBaseCoroutine::UnhandledException is raised at ::main, since it last resumed c.

```
• _CatchResume continues from resume (dynamic return, fixup)
```
• **catch** continues after handler (static return, recover)

• *The original exception’s (E) default terminate routine is not called because it has been caught and transformed.*

• *The coroutine terminates but control returns to its last resumer rather than its starter.*

• *Exception UnhandledException (and a few others) are always enabled.*

### 3.3 Memory Management

#### Normal Program Stack

- Normal program stack expands to heap; but coroutine stacks expand to next stack.

#### Multiple Coroutine Stacks

- In fact, coroutine stacks are normally allocated in the heap.
- Default \(\mu \text{C++} \) coroutine stack size is 64K and it does not grow.
- Adjust coroutine stack-size through coroutine constructor:

```cpp
_Coroutine C {
    public:
    C() : uBaseCoroutine(8192) { // default 8K stack
        C(int size) : uBaseCoroutine(size) { // user specified stack size
            ...
        }
    }
    C x, y(16384); // x has an 8K stack, y has a 16K stack
}
```

- Check for stack overflow using coroutine member verify:

```cpp
void main() {
    ...
    // declarations
    verify(); // check for stack overflow
    ...
    // code
}
```

- Be careful allocating arrays in the coroutine main; sometimes necessary to allocate large arrays in heap.

### 3.4 Semi-Coroutine Examples

#### 3.4.1 Same Fringe

- Two binary trees have same fringe if all leafs are equals from left to right.
• Requires iterator to traverse a tree, return the value of each leaf, and continue the traversal.

• No direct solution without using additional data-structure (e.g., stack) to manage the tree traversal.

• Coroutine uses recursive tree-traversal but suspends traversal to return value.

```cpp
template< typename T > class Btree {
    struct Node { . . . };  
    . . .
public:
    _Coroutine Iterator {
        Node * cursor;
        void walk( Node * node ) { // walk tree
            if ( node == nullptr ) return;
            if ( node->left == nullptr && node->right == nullptr ) { // leaf?
                cursor = node;
                suspend(); // multiple stack frames
            } else {
                walk( node->left ); // recursion
                walk( node->right); // recursion
            }
        }
    }
    void main() { walk( cursor ); cursor = nullptr; }
public:
    Iterator( Btree<T> & btree ) : cursor( &btree.root ) {} 
    T * next() {
        resume();
        return cursor;
    }
};

};
```

```cpp
template<class T> bool sameFringe( BTree<T> & tree1, BTree<T> & tree2 ) {
    BTree<T>::Iterator iter1( btree1 ), iter2( btree2 ); // iterator for each tree
    T * t1, * t2;
    for ( ;; ) {
        t1 = iter1.next(); t2 = iter2.next();
        if ( t1 == nullptr || t2 == nullptr ) break; // one traversal complete ?
        if ( *t1 != *t2 ) return false; // elements equal ?
    }
    return t1 == nullptr && t2 == nullptr; // and both traversals completed ?
}
```

### 3.4.2 Device Driver

• Called by interrupt handler for each byte arriving at hardware serial port.

• Parse transmission protocol and return message text, e.g.:

```
...STX...message...ESC ETX...message...ETX 2-byte CRC...
```
3.4. SEMI-COROUTINE EXAMPLES

3.4.2.1 Direct

```c
int main() {  
  enum { STX = '\002', ESC = '\033', ETX = '\003' };  
  enum { MaxMsgLnth = 64 };  
  unsigned char msg[MaxMsgLnth];  
  ...  
  try {  
    msg: for ( ;; ) {  
      int lnth = 0, checkval;  
      do {  
        byte = input( infile );  
      } while ( byte != STX );  
      // message start ?
      eom: for ( ;; ) {  
        // scan message data
        byte = input( infile );
      }  
      switch ( byte ) {  
        case STX:  
          ...  
          // protocol error
          continue msg;  
          // uC++ labelled continue
          break;
          // end of message
          break;
          case ETX:  
          break eom;  
          // uC++ labelled break
          break;
          case ESC:  
          byte = input( infile );  
          break;
          // escape next byte
        }  
        // switch
        if ( lnth >= 64 ) {  
          ...  
          // length error
          continue msg;  
          // uC++ labelled continue
        }  
        // if
        msg[lnth] = byte;  
        lnth += 1;
      }  
      // for
      byte = input( infile );  
      // gather check value
      checkval = byte;
      byte = input( infile );
      checkval = (checkval << 8) | byte;
      if ( ! crc( msg, lnth, checkval ) ) ... // CRC error
    }  
    // for
  } catch( Eof ) {}  
  ...  
} // main
```
3.4.2.2 Coroutine

Coroutine DeviceDriver {
    enum { STX = '\002', ESC = '\033', ETX = '\003' };
    unsigned char byte;
    unsigned char * msg;

    public:
        DeviceDriver( unsigned char * msg ) : msg( msg ) { resume(); }
        void next( unsigned char b ) { // called by interrupt handler
            byte = b;
            resume();
        }

    private:
        void main() {
            msg: for ( ; ; ) { // parse messages
                int lnth = 0, checkval;
                do {
                    suspend();
                } while ( byte != STX ); // message start ?
                eom: for ( ; ; ) { // scan message data
                    suspend();
                    switch ( byte ) {
                        case STX:
                            ... // protocol error
                            continue msg; // uC++ labelled continue
                        case ETX:
                            break eom; // uC++ labelled break
                        case ESC:
                            suspend(); // get escaped character
                            break;
                    } // switch
                } // for

                if ( lnth >= 64 ) { // buffer full ?
                    ... // length error
                    continue msg; // uC++ labelled continue
                } // if
                msg[lnth] = byte; // store message
                lnth += 1;
            } // for

            suspend(); // gather check value
            checkval = byte;
            suspend();
            checkval = (checkval << 8) | byte;
            if ( ! crc( msg, lnth, checkval ) ) ... // CRC error
        } // main
}; // DeviceDriver
3.4.3 Producer-Consumer

_Coroutine Cons {
  int p1, p2, status; bool done;
  void main() { // starter prod
    // 1st resume starts here
    int money = 1;
    for ( ; ! done; ) {
      cout << "cons " << p1 << " "
           << p2 << " pay $"
           << money << endl;
      status += 1;
      suspend(); // activate delivery or stop
      money += 1;
    }
    cout << "cons stops" << endl;
  } // suspend / resume(starter)
public:
  Cons() : status(0), done(false) {} 
  int delivery( int p1, int p2 ) {
    Cons::p1 = p1; Cons::p2 = p2;
    resume(); // activate main
    return status;
  }
  void stop() { done = true; resume(); } // activate main
};

_Coroutine Prod {
  Cons & c;
  int N;
  void main() { // starter ::main
    // 1st resume starts here
    for ( int i = 0; i < N; i += 1 ) {
      int p1 = rand() % 100; // products
      int p2 = rand() % 100;
      cout << "prod " << p1
           << " " << p2 << endl;
      int status = c.delivery( p1, p2 );
      cout << " stat " << status << endl;
    }
    c.stop();
    cout << "prod stops" << endl;
  } // suspend / resume(starter)
public:
  Prod( Cons & c ) : c(c) {}
  void start( int N ) {
    Prod::N = N;
    resume(); // activate main
  }
};
int main() {
    Cons cons; // create consumer
    Prod prod( cons ); // create producer
    prod.start( 5 ); // start producer
}

• Do both Prod and Cons need to be coroutines?
• When coroutine main returns, it activates the coroutine that started main.
• prod started cons.main, so control goes to prod suspended in stop.
• ::main started prod.main, so control goes back to ::main suspended in start.

• dashed red ⇒ create stack and resume coroutine main
• solid red ⇒ resume coroutine at last suspend
• solid blue ⇒ resume last resumer
• dashed blue ⇒ resume starter

3.5 Full Coroutines
• Semi-coroutine activates the member routine that activated it.
• Full coroutine has a resume cycle; semi-coroutine does not form a resume cycle.
3.5. FULL COROUTINES

- A full coroutine is allowed to perform semi-coroutine operations because it subsumes the notion of semi-coroutine.

```cpp
_Coroutine Fc {
    void main() { // starter ::main
        mem(); // ?
        resume(); // ?
        suspend(); // ?
    }
    public:
        void mem() { resume(); }
};
int main() {
    Fc fc;
    fc.mem();
}
```

- Suspend inactivates the current active coroutine (uThisCoroutine), and activates last resumer.

- Resume inactivates the current active coroutine (uThisCoroutine), and activates the current object (this).
• Hence, the current object must be a non-terminated coroutine.

• Note, this and uThisCoroutine change at different times.

• Exception: last resumer not changed when resuming self because no practical value.

• Full coroutines can form an arbitrary topology with an arbitrary number of coroutines.

• There are 3 phases to any full coroutine program:
  
  1. starting the cycle
  2. executing the cycle
  3. stopping the cycle (return to the program main)

• Starting the cycle requires each coroutine to know at least one other coroutine.

• The problem is mutually recursive references:

  \[ \text{FC } x(y), \ y(x); \]

• One solution is to make closing the cycle a special case:

  \[ \text{FC } x, \ y(x); \]
  \[ x.\text{partner}(y); \]

• Once the cycle is created, execution around the cycle can begin.

• Stopping can be as complex as starting, because a coroutine goes back to its starter.

• A starter coroutine is the coroutine that does the first resume (cocall).

• For semi-coroutines, the starter is often the last (only) resumer, so it seems coroutine main implicitly suspends on termination.

• For full-coroutines, the starter is often not the last resumer, so it does not seem coroutine main implicitly suspends on termination.

• In many cases, it is unnecessary to terminate all coroutines, just delete them.

• But it is necessary to activate the program main to finish (unless exit is used).

3.5.1 Ping/Pong

• Full-coroutine control-flow: 2 identical coroutines:

  creation \[\text{::main} \]
  |      |
  |      |
  ping   pong

  starter \[\text{::main} \]
  |      |
  |      |
  ping   pong

  execution \[\text{::main} \]
  |      |
  |      |
  ping   pong
3.5. FULL COROUTINES

Coroutine PingPong {
    const char * name;
    const unsigned int N;
    PingPong * part;
    void main() {
        // ping' s starter ::main, pong' s starter ping
        for ( unsigned int i = 0; i < N; i += 1 ) {
            cout << name << endl;
            part->cycle();
        }
    }

    public:
    PingPong( const char * name, unsigned int N, PingPong & part )
        : name( name ), N(N), part( & part ) {}
    PingPong( const char * name, unsigned int N )
        : name( name ), N(N) {}
    void partner( PingPong & part ) { PingPong::part = &part; }
    void cycle() { resume(); }
};

int main() {
    enum { N = 20 };
    PingPong ping( "ping", N ), pong( "pong", N, ping );
    ping.partner( pong );
    ping.cycle();
}

• ping created without partner; pong created with partner.

• ping makes pong partner, closing cycle.

• Why is PingPong::part a pointer rather than reference?

  • cycle resumes ping ⇒ ::main is ping’s starter

  • ping calls pong’s cycle member, resuming pong so ping is pong’s starter.

  • pong calls ping’s cycle member, **resuming ping in pong’s cycle member**.

  • Each coroutine cycles N times, becoming inactive in the other’s cycle member.

• ping ends first, because it started first, resuming its starter ::main in ping’s cycle member.

  • ::main terminates with terminated coroutine ping and unterminated coroutine pong.

  • Assume ping’s declaration is changed to ping( "ping", N + 1 ).

  • pong ends first, resuming its starter ping in pong’s cycle member.

  • ping ends second, resuming its starter ::main in ping’s cycle member.

  • ::main terminates with terminated coroutines ping and pong.
3.5.2 Producer-Consumer

- Full-coroutine control-flow and bidirectional communication: 2 non-identical coroutines:

```cpp
Coroutine Prod {  
    Cons * c;
    int N, money, receipt;
    void main() {  // starter ::main  
        // 1st resume starts here
        for ( int i = 0; i < N; i += 1 ) {  
            int p1 = rand() % 100;  // products
            int p2 = rand() % 100;
            cout << "prod " << p1  
                << " prod rec $" << money  
                << " prod stops" << endl;
            receipt += 1;
        }
    c->stop();
    cout << "prod stops" << endl;
    }
    
    public:
    int payment( int money ) {  
        Prod::money = money;
        resume();  // Prod::main 1st time, then
        return receipt;  // prod in Cons::delivery
    }
    void start( int N, Cons & c ) {  
        Prod::N = N;  Prod::c = &c;
        receipt = 0;
        resume();  // activate main
    }
};
```
3.5. FULL COROUTINES

_Coroutine Cons {
Prod & p;
int p1, p2, status;
bool done;
void main() {
    // starter prod
    // 1st resume starts here
    int money = 1, receipt;
    for ( ; ! done; ) {
        cout << "cons " << p1 << " "
            << p2 << " pay $"
            << money << endl;
        status += 1;
        receipt = p.payment(money);
        cout << "cons #"
            << receipt << endl;
        money += 1;
    }
    cout << "cons stops" << endl;
}

public:
Cons(Prod & p) : p(p), status(0), done(false) {}
int delivery( int p1, int p2 ) {
    Cons::p1 = p1; Cons::p2 = p2;
    resume(); // Cons::main 1st time, then
    return status; // cons in Prod::payment
}
void stop() {
    done = true;
    resume(); // activate Prod::payment
}
};
int main() {
    Prod prod;
    Cons cons( prod );
    prod.start( 5, cons );
}

• Cheat using forward reference for Cons at c->delivery and c->stop. Fix by?

• Remove flag variable from full-coroutine producer-consumer.
3.6 Coroutine Languages

- Coroutine implementations have two forms:

  1. stackless: use the caller’s stack and a fixed-sized local-state
  2. stackful: separate stack and a fixed-sized local-state

- Stackless coroutines cannot call other routines and then suspend, i.e., only suspend in the coroutine main.

- Generators/iterators are often simple enough to be stackless using yield.

- Simula, CLU, C#, Ruby, Python, JavaScript, Lua, F#, Boost all support yield constructs.

3.6.1 Python 3.4.1

- Stackless, semi coroutines, routine versus class, no calls, single interface

- Fibonacci (see Section 3.1.1.4, p. 32)
def Fibonacci(n):
    fn = 0; fn1 = fn
    yield fn
    fn = 1; fn2 = fn1; fn1 = fn
    yield fn
    # while True:
    for i in range(n-2):
        fn = fn1 + fn2; fn2 = fn1; fn1 = fn
        yield fn
    f1 = Fibonacci(10)
    f2 = Fibonacci(10)
    for i in range(10):
        print(next(f1), next(f2))
    for fib in Fibonacci(15):
        print(fib)

• Format (see Section 3.1.2.4, p. 36)

def Format():
    try:
        while True:
            for g in range(5):
                for b in range(4):
                    print((yield), end='') # receive from send
                print(' ', end='') # block separator
            print() # group separator
        except GeneratorExit:
            if g != 0 | b != 0:
                print() # special case

    fmt = Format()
    next(fmt) # prime generator
    for i in range(41):
        fmt.send('a') # send to yield

• send takes only one argument, and no cycles ⇒ no full coroutine

3.6.2 C++ Boost Library (V1.61)

• stackfull, semi/full coroutines, routine versus class, single interface

• return activates creator

• full coroutine uses resume( partner, ... ), specifying target coroutine to be activated

• coroutine state passed as explicit parameter

• Fibonacci (semi-coroutine, asymmetric)
int fibonacci( coroutine< int >::push_type & suspend ) {
    int fn = 0, fn1 = fn, fn2;  // 1st case
    suspend( fn );
    fn = 1; fn2 = fn1; fn1 = fn;  // 2nd case
    suspend( fn );
    for ( ;; ) {
        fn = fn1 + fn2; fn2 = fn1; fn1 = fn;  // general case
        suspend( fn );
    }
}

int main() {
    coroutine< int >::pull_type fib( fibonacci );
    // declaration does first resume
    for ( int i = 0; i < 15; i += 1 ) {
        cout << fib.get() << " ";  // get output
        fib();  // resume
    }
    cout << endl;
}

• Formatter (semi-coroutine, asymmetric)

void format( coroutine< char >::pull_type & suspend ) {
    int g, b;  char ch;
    for ( ;; ) {
        for ( g = 0; g < 5; g += 1 ) {
            for ( b = 0; b < 4; b += 1 ) {
                for ( ;; ) {
                    ch = suspend.get();  // get input
                    if ( ch == '\377' ) goto fini;  // end of input ?
                    suspend();
                    if ( ch != '\n' ) break;  // ignore newline
                }
                cout << ch;  // print character
            }
            cout << " ";  // print block separator
        }
        cout << endl;  // print group separator
    }
    fini:
    if ( g != 0 || b != 0 ) cout << endl;  // special case
3.6. COROUTINE LANGUAGES

```c++
int main() {
    coroutine< char >::push_type fmt( format );
    char ch;
    cin >> noskipws;               // no white space skipping
    for ( ;; ) {
        cin >> ch;                  // read one character
        if ( cin.fail() ) break;    // eof ?
        fmt( ch );
    }
    fmt( '\377' );              // resume senetential
}
```

- Producer/Consumer (full-coroutine, symmetric)

```c++
typedef tuple< int, int, int > ConsParms;
typedef tuple< int, int > ProdParms;
typedef symmetric_coroutine< ConsParms > Cons;
typedef symmetric_coroutine< ProdParms > Prod;

void prod_main( Prod::yield_type & resume, Cons::call_type & cons ) {
    int money, status, receipt = 0;
    for ( int i = 0; i < 5; i += 1 ) {
        int p1 = rand() % 100, p2 = rand() % 100;
        cout << "prod delivers " << p1 << ", " << p2 << endl;
        tie( money, status ) = resume( cons, { p1, p2, receipt } ).get();
        cout << "prod gets money $" << money << " status " << status << endl;
        receipt += 1;
    }
    resume( cons, { -1, -1, -1 } );
    cout << "prod stops" << endl;
}

void cons_main( Cons::yield_type & resume, Prod::call_type & prod ) {
    int p1, p2, receipt, money = 1, status = 0;
    for ( int i = 0; i < 5; i += 1 ) {
        tie( p1, p2, receipt ) = resume.get();
        cout << "cons receives " << p1 << ", " << p2 << 
             " and pays $" << money << " gets receipt #" << receipt << endl;
        status += 1;
        resume( prod, { money, status } );
        money += 1;
    }
    cout << "cons stops" << endl;
    resume( prod, { -1, -1 } );
}
```
int main() {
    Prod::call_type prod;
    Cons::call_type cons;
    // lambda contains partner in closure
    prod = Prod::call_type(
        [&]( Prod::yield_type & resume ) { prod_main( resume, cons ); } );
    cons = Cons::call_type(
        [&]( Cons::yield_type & resume ) { cons_main( resume, prod ); } );
    prod( { -1, -1 } );
}
4 More Exceptions

4.1 Derived Exception-Type

- **derived exception-types** is a mechanism for inheritance of exception types, like inheritance of classes.

- Provides a kind of polymorphism among exception types:

  ![Exception Hierarchy Diagram]

- Provides ability to handle an exception at different degrees of specificity along the hierarchy.

- Possible to catch a more general exception-type in higher-level code where the implementation details are unknown.

- Higher-level code should catch general exception-types to reduce tight coupling to the specific implementation.
  - tight coupling may force unnecessary changes in the higher-level code when low-level code changes.

- Exception-type inheritance allows a handler to match multiple exceptions, e.g., a base handler can catch both base and derived exception-type.

- To handle this case, most propagation mechanisms perform a linear search of the handlers for a guarded block and select the first matching handler.

  ```
  try { . . .
  } catch( Arithmetic ) { . . .
  } catch( Overflow ) { . . . // never selected!!!
  }
  ```

- When subclassing, it is best to catch an exception by reference:

  ```
  struct B {};
  struct D : public B {};
  try {
    try {
      throw D(); // _Throw in uC++
    } catch( B & e ) { // truncation
      // cannot down-cast
    } catch( B e ) { // truncation
      // cannot down-cast
    } catch( D & e ) { // no truncation
      . . .
    } catch( D e ) { // no truncation
      . . .
    } catch( dynamic_cast<D>(e) ) . . .
  }
  ```

  - Otherwise, exception is truncated from its dynamic type to static type specified at the handler, and cannot be down-cast to the dynamic type.
4.2 Catch-Any

- **catch-any** is a mechanism to match any exception propagating through a guarded block.
- For termination, catch-any is used as a general cleanup when a non-specific exception occurs.
- For resumption, this capability allows a guarded block to gather or generate information about control flow.
- With exception-type inheritance, catch-any can be provided by the root exception-type, e.g., `catch( Exception )` in Java.
- Otherwise, special syntax is needed, e.g., `catch( . . . )` in C++.
- Java finalization:
  ```java
  try { . . . }
  catch( E ) { . . . }
  . . . // other catch clauses
  finally { . . . } // always executed
  ```
  provides additional catch-any capabilities and handles the non-exceptional case.
  - difficult to mimic in C++, even with RAII, because of local variables.

4.3 Exception Parameters

- **Exception parameters** allow passing information from the raise to a handler.
- Inform a handler about details of the exception, and to modify the raise site to fix an exceptional situation.
- Different EHMs provide different ways to pass parameters.
- In C++/Java, parameters are defined inside the exception:
  ```java
  struct E {
    int i;
    E( int i ) : i(i) {} 
  };
  void f(...) { . . . throw E( 3 ); . . . } // argument
  int main() {
    try {
      f(...);
    } catch( E p ) { // parameter
      // use p.i
    }
  }
  ```
- For resumption, values at raise modified via reference/pointer in caught exception:
4.4 Exception List

- Missing exception handler for arithmetic overflow in control software caused Ariane 5 rocket to self-destruct ($370 million loss).

- **exception list** is part of a routine’s prototype specifying which exception types may propagate from the routine to its caller.

  ```
  int g() throw(E) { ... throw E(); }
  ```

  - This capability allows:
    - static detection of a raised exception not handled locally or by its caller
    - runtime detection where the exception may be converted into a special failure exception or the program terminated.

- 2 kinds of checking:
  - checked/unchecked exception-type (Java, inheritance based, static check)
  - checked/unchecked routines (C++, exception-list based, dynamic check) (deprecated C++11, replaced with noexcept)

- While checked exception-types are useful for software engineering, reuse is precluded.

- E.g., consider the simplified C++ template routine sort:

  ```
  template<class T> void sort( T items[] ) throw( ?, ?, ... ) {
    // using bool operator<( const T &a, const T &b );

  ```

  using the operator routine < in its definition.

- Impossible to know all exception types that propagated from routine < for every type.
• Since only a fixed set of exception types can appear in sort’s exception list, some sortable types are precluded.

• Exception lists can preclude reuse for arguments of routine pointers (functional style) and/or polymorphic methods/routines (OO style):

```cpp
// throw NO exceptions
void f(void (*)() throw()) {
    p();
}
void g() throw(E) { throw E(); }
void h() {
    try { ... f( g ); ... }
    catch( E ) {} }
}

struct B { // throw NO exceptions
    virtual void g() throw() {}
    void f() { g(); }
};
struct D : public B {
    void g() throw(E) { throw E(); }
    void h() {
        try { ... f(); ... }
        catch( E ) {} }
};

• Left example, routine h has an appropriate try block and passes the version of g to f that raises exception-type E.

• However, checked exception-types preclude this case because the signature of argument g is less restrictive than parameter p of f.

• Right example, member routine D::h calls B::f, which calls D::g that raises exception-type E.

• However, checked exception types preclude this case because the signature of D::g is less restrictive than B::g.

• Finally, determining an exception list for a routine can become impossible for concurrent exceptions because they can propagate at any time.

4.5 Destructor

• Destructor is implicitly noexcept ⇒ cannot raise an exception.

• Destructor can raise an exception, if marked noexcept(false), or inherits from class with noexcept(false) destructor.

```cpp
struct E {};
struct C {
    ~C() noexcept(false) { throw E(); }
}
try {
    C x; // raise on deallocation
    try {
        C y; // raise on deallocation
        } catch( E ) {...} // inner handler
    } catch( E ) {...} // outer handler
```
4.5. Destructor

- Y’s destructor called at end of inner try block, it raises an exception E, which unwinds destructor and try, and handled at inner catch
- X’s destructor called at end of outer try block, it raises an exception E, which unwinds destructor and try, and handled at outer catch

- A destructor cannot raise an exception during propagation.

```cpp
try {
    C x; // raise on deallocation
    throw E();
} catch (E) {...}
```

- Raise of E causes unwind of inner try block.

- X’s destructor called during unwind, it raises an exception E, which one should be used?
  - Cannot start second exception without handler to deal with first exception, i.e., cannot drop exception and start another.
  - Cannot postpone first exception because second exception may remove its handlers during stack unwinding.

- Check if exception is being propagated with uncaught_exception().
5 Concurrency

- A thread is an independent sequential execution path through a program. Each thread is scheduled for execution separately and independently from other threads.

- A process is a program component (like a routine) that has its own thread and has the same state information as a coroutine.

- A task is similar to a process except that it is reduced along some particular dimension (like the difference between a boat and a ship, one is physically smaller than the other). It is often the case that a process has its own memory, while tasks share a common memory. A task is sometimes called a light-weight process (LWP).

- Parallel execution is when 2 or more operations occur simultaneously, which can only occur when multiple processors (CPUs) are present.

- Concurrent execution is any situation in which execution of multiple threads appears to be performed in parallel. It is the threads of control associated with processes and tasks that results in concurrent execution.

5.1 Why Write Concurrent Programs

- Dividing a problem into multiple executing threads is an important programming technique just like dividing a problem into multiple routines.

- Expressing a problem with multiple executing threads may be the natural (best) way of describing it.

- Multiple executing threads can enhance execution-time efficiency by taking advantage of inherent concurrency in an algorithm and any parallelism available in the computer system.

5.2 Why Concurrency is Difficult

- to understand:
  - While people can do several things concurrently, the number is small because of the difficulty in managing and coordinating them.
  - Especially when the things interact with one another.

- to specify:
  - How can/should a problem be broken up so that parts of it can be solved at the same time as other parts?
  - How and when do these parts interact or are they independent?
  - If interaction is necessary, what information must be communicated during the interaction?

- to debug:
Concurrent operations proceed at varying speeds and in non-deterministic order, hence execution is not repeatable (Heisenbug).

Reasoning about multiple streams or threads of execution and their interactions is much more complex than for a single thread.

- E.g. Moving furniture out of a room; can’t do it alone, but how many helpers and how to do it quickly to minimize the cost.

- How many helpers?
  - 1, 2, 3, ..., N, where N is the number of items of furniture
  - more than N?

- Where are the bottlenecks?
  - the door out of the room, items in front of other items, large items

- What communication is necessary between the helpers?
  - which item to take next
  - some are fragile and need special care
  - big items need several helpers working together

5.3 Concurrent Hardware

- Concurrent execution of threads is possible with only one CPU (uniprocessor); multitasking for multiple tasks or multiprocessing for multiple processes.

- Parallelism is simulated by context switching the threads on the CPU.
- Most of the issues in concurrency can be illustrated without parallelism.
- Pointers among tasks work because memory is shared.
- Unlike coroutines, task switching may occur at non-deterministic program locations, i.e., between any two machine instructions.
- Introduces all the difficulties in concurrent programs.
  - * programs must be written to work regardless of non-deterministic ordering of program execution.
  - Switching happens explicitly but conditionally when calling routines.
5.3. CONCURRENT HARDWARE

- routine may or may not context switch depending on hidden (internal) state (cannot predict)
  - Switching can happen *implicitly* because of an external *interrupt* independent of program execution.
    - e.g., I/O or timer interrupt;
    - timer interrupts divide execution (between instructions) into discrete time-slices occurring at non-deterministic time intervals
    - ⇒ task execution is not continuous
  - If interrupts affect *scheduling* (execution order), it is called *preemptive*, otherwise the scheduling is *non-preemptive*.
  - Programmer cannot predict execution order, unlike coroutines.
  - Granularity of context-switch is instruction level for preemptive (harder to reason) and routine level for non-preemptive.

- In fact, every computer has multiple CPUs: main CPU(s), bus CPU, graphics CPU, disk CPU, network CPU, etc.

- Concurrent/parallel execution of threads is possible with multiple CPUs sharing memory (*multiprocessor*):

  ![Diagram of concurrent execution](image)

  - Pointers among tasks work because memory is shared.

- Concurrent/parallel execution of threads is possible with single/multiple CPUs on different computers with *separate memories* (*distributed system*):

  ![Diagram of distributed execution](image)

  - Pointers among tasks do NOT work because memory is not shared.
5.4 Execution States

- A thread may go through the following states during its execution.

![State Transition Diagram]

- **State transitions** are initiated in response to events (interrupts):
  
  - timer alarm (running $\rightarrow$ ready)
  - completion of I/O operation (blocked $\rightarrow$ ready)
  - exceeding some limit (CPU time, etc.) (running $\rightarrow$ halted)
  - error (running $\rightarrow$ halted)

- Non-deterministic “ready $\leftrightarrow$ running” transition $\Rightarrow$ basic operations unsafe:

  ```
  int i = 0;    // shared
  task0
  i += 1        // shared
  task1
  i += 1
  ```

- If increment implemented with single `inc i` instruction, transitions can only occur before or after instruction, not during.

- If increment is replaced by a load-store sequence, transitions can occur during sequence.

  ```
  ld r1,i       // load into register 1 the value of i
  ...           // PREEMPTION
  add r1,#1     // add 1 to register 1
  ...           // PREEMPTION
  st r1,i       // store register 1 into i
  ```

- If both tasks increment 10 times, the expected result is 20.

- True for single instruction, false for load-store sequence.

- Many failure cases for load-store sequence where i does not reach 20.

- Remember, context switch saves and restores registers for each coroutine/task.
5.5. Threading Model

- For multiprocessor systems, a threading model defines relationship between threads and CPUs.

- OS manages CPUs providing logical access via kernel threads (virtual processors) scheduled across the CPUs.

- More kernel threads than CPUs to provide multiprocessing, i.e., run multiple programs simultaneously.
A process may have multiple kernel threads to provide parallelism if multiple CPUs.

A program may have user threads scheduled on its process's kernel threads.

User threads are a low-cost structuring mechanism, like routines, objects, coroutines (versus high-cost kernel thread).

Relationship is denoted by user:kernel:CPU, where:

- 1:1:C (kernel threading) – 1 user thread maps to 1 kernel thread
- N:N:C (generalize kernel threading) – N × 1:1 kernel threads (Java/Pthreads)
- M:1:C (user threading) – M user threads map to 1 kernel thread (no parallelism)
- M:N:C (user threading) – M user threads map to N kernel threads (Go, µC++)

Often the CPU number (C) is omitted.

Can recursively add nano threads on top of user threads, and virtual machine below OS.

5.6 Concurrent Systems

Concurrent systems can be divided into 3 major types:

1. those that attempt to discover concurrency in an otherwise sequential program, e.g., parallelizing loops and access to data structures
2. those that provide concurrency through implicit constructs, which a programmer uses to build a concurrent program
3. those that provide concurrency through explicit constructs, which a programmer uses to build a concurrent program

In type 1, there is a fundamental limit to how much parallelism can be found and current techniques only work on certain kinds of programs.

In type 2, concurrency is accessed indirectly via specialized mechanisms (e.g., pragmas or parallel for) and implicitly managed.

In type 3, concurrency is directly accessed and explicitly managed.

Cases 1 & 2 are always built from type 3.

To solve all concurrency problems, threads need to be explicit.

Both implicit and explicit mechanisms are complementary, and hence, can appear together in a single programming language.

However, the limitations of implicit mechanisms require that explicit mechanisms always be available to achieve maximum concurrency.

Some concurrent systems provide a single technique or paradigm that must be used to solve all concurrent problems.
• While a particular paradigm may be very good for solving certain kinds of problems, it may be awkward or preclude other kinds of solutions.

• Therefore, a good concurrent system must support a variety of different concurrent approaches, while at the same time not requiring the programmer to work at too low a level.

• In all cases, as concurrency increases, so does the complexity to express and manage it.

5.7 Speedup

• Program speedup is $S_C = T_1 / T_C$, where $C$ is number of CPUs and $T_1$ is sequential execution.

• E.g., 1 CPU takes 10 seconds, $T_1 = 10$ (user time), 4 CPUs takes 2.5 seconds, $T_4 = 2.5$ (real time) $\Rightarrow S_4 = 10/2.5 = 4$ times speedup (linear).

\[
\begin{align*}
S_C = T_1 / T_C \\
\text{super linear } S_C > C \\
\text{linear } S_C = C \\
\text{sub-linear } S_C < C \\
\text{non-linear } S_C < C \\
\end{align*}
\]

• Aspects affecting speedup (assume sufficient parallelism for concurrency):
  1. amount of concurrency
  2. critical path among concurrency
  3. scheduler efficiency

• An algorithm/program is composed of sequential and concurrent sections.

• E.g., sequentially read matrix, concurrently subtotal rows, sequentially total subtotals.

• **Amdahl’s law** (Gene Amdahl): concurrent section of program is $P$ making sequential section $1 - P$, then maximum speedup using $C$ CPUs is:

\[
S_C = \frac{1}{(1-P) + P/C} \text{ where } T_1 = 1, T_C = \text{sequential + concurrent}
\]

• As $C$ goes to infinity, $P/C$ goes to 0, so maximum speedup is $1/(1 - P)$, i.e., time for sequential section.

• Speedup falls rapidly as sequential section $(1 - P)$ increases, especially for large $C$. 
• E.g., sequential section = 0.1 (10%), $S_C = 1/(1 - 0.9) \Rightarrow$ max speedup 10.

• Concurrent programming consists of minimizing sequential component $(1 - P)$.

• E.g., an algorithm/program has 4 stages: $t_1 = 10$, $t_2 = 25$, $t_3 = 15$, $t_4 = 50$ (time units)

• Concurrently speedup sections $t_2$ by 5 times and $t_4$ by 10 times.

\[ T_C = 10 + 25/5 + 15 + 50/10 = 35 \text{ (time units)} \]

Speedup = $100 / 35 = 2.86$ times

• Large reductions for $t_2$ and $t_4$ have only minor effect on speedup.

• Formula does not consider any increasing costs for the concurrency, i.e., administrative costs, so results are optimistic.

• While sequential sections bound speedup, concurrent sections bound speedup by the **critical path** of computation.

• **Independent execution**: all threads created together and do not interact.

• **Dependent execution**: threads created at different times and interact.

• Longest path bounds speedup.

• Finally, speedup can be affected by scheduler efficiency/ordering (often no control), e.g.:

  - greedy scheduling: run a thread as long as possible before context switching (not very concurrent).
  - LIFO scheduling: give priority to newly waiting tasks (starvation).

• Therefore, it is difficult to achieve significant speedup for many algorithms/programs.

• In general, benefit comes when many programs achieve some speedup so there is an overall improvement on a multiprocessor computer.
5.8 Thread Creation

- Concurrency requires 3 mechanisms in a programming language.

  1. creation – cause another thread of control to come into existence.
  2. synchronization – establish timing relationships among threads, e.g., same time, same rate, happens before/after.
  3. communication – transmit data among threads.

- Thread creation must be a primitive operation; cannot be built from other operations in a language.

- ⇒ need new construct to create a thread and define where the thread starts execution.

5.8.1 COBEGIN/COEND

- Compound statement with statements run by multiple threads.

```
#include <uCobegin.h>

int i;
void p1(...);
void p2(...);
void p3(...);

// initial thread creates threads
COBEGIN // threads execute statement in block
  BEGIN i = 1; ... END
  BEGIN p1(5); ... END // order and speed of internal
  BEGIN p2(7); ... END // thread execution is unknown
  BEGIN p3(9); ... END
COEND // initial thread waits for all internal threads to
      // finish (synchronize) before control continues
```

- implicit or explicit concurrency?

- A thread graph represents thread creations:

- Restricted to creating trees (lattice) of threads.
• Use recursion to create dynamic number of threads.

```cpp
void loop( int N ) {
    if ( N != 0 ) {
        COBEGIN
            BEGIN p1( . . . ); END
            BEGIN loop( N - 1 ); END // recursive call
        COEND // wait for return of recursive call
    }
}
```

cin >> N;
loop( N );

• What does the thread graph look like?

5.8.2 START/WAIT

• Start thread in routine and wait (join) at thread termination, allowing arbitrary thread graph:

```
#include <uCobegin.h>
int i;
void p( int i ) {...}
int f( int i ) {...}
auto tp = START( p, 5 ); thread starts in p(5)
s1 continue execution, do not wait for p
auto tf = START( f, 8 ); thread starts in f(8)
s2 continue execution, do not wait for f
WAIT( tp ); wait for p to finish
s3
i = WAIT( tf ); wait for f to finish
s4
```

• implicit or explicit concurrency?

• COBEGIN/COEND can only approximate this thread graph:

```
COBEGIN
    BEGIN p( 5 ); END
    BEGIN s1; COBEGIN BEGIN f( 8 ); s2; END COEND END // wait for f!
COEND
s3; s4;
```

• START/WAIT can simulate COBEGIN/COEND:

```
COBEGIN
    BEGIN p1( . . . ) END
    BEGIN p2( . . . ) END
    auto t1 = START( p1, . . . )
    auto t2 = START( p2, . . . )
    WAIT t1
    WAIT t2
```

5.8.3 Thread Object

• C++ is an object-oriented programming language, which suggests:
5.8. THREAD CREATION

- wrap the thread in an object to leverage all class features
- use object allocation/deallocation to define thread lifetime rather than control structure

```cpp
_Task T { // thread type
    void main() {...} // thread starts here
};
COBEGIN {
    // { int i, j, k; } ???
    T t; // create object on stack, start thread
COEND } // wait for thread to finish
START T * t = new T; // create thread object on heap, start thread
WAIT delete t; // wait for thread to finish
```

- Block-terminate/delete must wait for each task’s thread to finish. Why?
- Unusual to:
  - create objects in a block and not use it
  - allocate object and immediately delete it.
- Simulate COBEGIN/COEND with _Task object by creating type for each statement:

```cpp
int i;
_Task T1 {
    void main() { i = 1; }
};
_Task T2 {
    void main() { p1(5); }
};
_Task T3 {
    void main() { p2(7); }
};
_Task T4 {
    void main() { p3(9); }
};
```

- Simulate START/WAIT with _Task object by creating type for each call:

```cpp
int i;
_Task T1 {
    void main() { p(5); }
};
_Task T2 {
    int temp;
    void main() { temp = f(8); }
    public:
    ~T2() { i = temp; }
};
```

- Variable i cannot be assigned until tf is deleted, otherwise the value could change in s2/s3.
- Allows same routine to be started multiple times with different arguments.
5.8.4 Actor

- An **actor** (Hewitt/Agha) is a unit of work without a thread.
- Two popular programming languages with actors are Erlang and Scala.
- Communication is via polymorphic queue of messages (mailbox) ⇒ dynamic type-checking.

```
#include <uActor.h>

struct StrMsg : public uActor::Message { // derived message
  string val; // string message
  StrMsg( string val ) : Message( uActor::Delete ), // delete after use
    val( val ) {}
};

_Actor Hello {
  Allocation receive( Message & msg ) { // receive base type
    Case( StrMsg, msg ) { // discriminate derived message
      ... msg_d->val; ... // access derived message
    } else Case( StopMsg, msg ) return Delete; // delete actor
    return Nodelete; // reuse actor
  }
}

int main() { // like COBEGIN / COEND
  *(new Hello()) | *new StrMsg( "hello" ) | uActor::stopMsg;
  *(new Hello()) | *new StrMsg( "bonjour" ) | uActor::stopMsg;
  uActor::stop(); // wait for all actors to terminate
}
```

- Actors and messages are dynamically allocated by programmer and (usually) deallocated by worker pool.
  - actor indicates **Delete** / **Nodelete** after each receive.
  - derived message marked persist (**Nodelete**, default) or one-shot (**Delete**) at construction
- (StartMsg) **uActor::startMsg** / (StopMsg) **uActor::stopMsg** persistent predefined messages.
- Received derived message accessed through name **msg_d**.
- Send messages with operator |.
- Must wait for actors to complete (**uActor::stop()**).
5.9 Termination Synchronization

- A thread terminates when:
  - it finishes normally
  - it finishes with an error
  - it is killed by its parent (or sibling) (not supported in μC++)
  - because the parent terminates (not supported in μC++)

- Children can continue to exist even after the parent terminates (although this is rare).
  - E.g. sign off and leave child process(es) running

- Synchronizing at termination is possible for independent threads.

- Termination synchronization may be used to perform a final communication.

5.10 Divide-and-Conquer

- Divide-and-conquer is characterized by ability to subdivide work across data ⇒ work can be performed independently on the data.

- Work performed on each data group is identical to work performed on data as whole.

- Taken to extreme, each data item is processed independently, but administration of concurrency becomes greater than cost of work.

- Only termination synchronization is required to know when the work is done

- Partial results are then processed further if necessary.

- Sum rows of a matrix concurrently using concurrent statement:

```
#include <uCobegin.h>
int main() {
    const int rows = 10, cols = 10;
    int matrix[rows][cols], subtotals[rows], total = 0;
    // read matrix
    COFOR( r, 0, rows,
        // for ( int r = 0; r < rows; r += 1 )
        subtotals[r] = 0; // r is loop number
        for ( int c = 0; c < cols; c += 1 )
            subtotals[r] += matrix[r][c];
    ); // wait for threads
    for ( int r = 0; r < rows; r += 1 ) {
        total += subtotals[r]; // total subtotals
    }
    cout << total << endl;
}
```

- COFOR creates end – start threads, named start..end – 1, each executing loop body.
• implicit or explicit concurrency?

• Sum rows of a matrix concurrently using actors:

```cpp
_AnActor Adder {
   int * row, cols, & subtotal; // communication
   Allocation receive( Message & ) { // only startMsg
      subtotal = 0;
      for ( int c = 0; c < cols; c += 1 ) subtotal += row[c];
      return Delete; // delete actor (match new)
   }

   public:
   Adder( int row[], int cols, int & subtotal ) :
      row( row ), cols( cols ), subtotal( subtotal ) {}
};

int main() {
   ... // same
   for ( int r = 0; r < rows; r += 1 ) { // actor per row
      *(new Adder( matrix[r], cols, subtotals[r] )) | uActor::startMsg;
   }
   uActor::stop(); // wait for all actors to terminate
   ... // same
} // main
```

• implicit or explicit concurrency?

• Sum rows of a matrix concurrently using concurrent objects:

```cpp
_Task Adder {
   int * row, cols, & subtotal; // communication
   void main() {
      subtotal = 0;
      for ( int c = 0; c < cols; c += 1 ) subtotal += row[c];
   }

   public:
   Adder( int row[], int cols, int & subtotal ) :
      row( row ), cols( cols ), subtotal( subtotal ) {}
};

int main() {
   ... // same
   Adder * adders[rows];
   for ( int r = 0; r < rows; r += 1 ) { // start threads to sum rows
      adders[r] = new Adder( matrix[r], cols, subtotals[r] );
   }
   for ( int r = 0; r < rows; r += 1 ) { // wait for threads to finish
      delete adders[r];
      total += subtotals[r]; // total subtotals
   }
   cout << total << endl;
}
```

• implicit or explicit concurrency?
5.11 Exceptions

- Exceptions can be handled locally within a task, or nonlocally among coroutines, or concurrently among tasks.
  - All concurrent exceptions are nonlocal, but nonlocal exceptions can also be sequential.
- Local task exceptions are the same as for a class.
  - An unhandled exception raised by a task terminates the program.
- Nonlocal exceptions are possible because each coroutine/task has its own stack (execution state)
- Nonlocal exceptions between a task and a coroutine are the same as between coroutines (single thread).
- Concurrent exceptions among tasks are more complex due to the multiple threads.
- A concurrent exception provides an additional kind of communication among tasks.

- For example, two tasks may begin searching for a key in different sets:

```cpp
_Event StopEvent {};  
_Task Searcher { 
    Searcher * partner; 
    void main() { 
        try { 
            _Enable {  
                // allow nonlocal exceptions
                ..  
                // search
                if ( key == .. ) {  
                    _Resume StopEvent() _At partner;  
                    // stop partner
                    _Throw StopEvent();  
                    // stop me
                }
            }
        } 
        catch( StopEvent ) {..}  
        // reset for next search
    }
}
```

- When one task finds the key, it informs the other task to stop searching.
- For a concurrent raise, the source execution may only block while queueing the event for delivery at the faulting execution.
- After event is delivered, faulting execution propagates it at soonest opportunity (e.g., next context switch); i.e., faulting task polls; it is not interrupted.
5.12 **Synchronization and Communication During Execution**

- Synchronization occurs when one thread waits until another thread has reached a certain execution point (state and code).

- One place synchronization is needed is in transmitting data between threads.
  - One thread has to be ready to transmit the information and the other has to be ready to receive it, simultaneously.
  - Otherwise one might transmit when no one is receiving, or one might receive when nothing is transmitted.

```cpp
bool Insert = false, Remove = false;
int Data;

_Task Prod {
    int N;
    void main() {
        for ( int i = 1; i <= N; i += 1 ) {
            Data = i; // transfer data
            Insert = true;
            while ( ! Remove ) {} // busy wait
            Remove = false;
        }
    }

    public:
    Prod( int N ) : N( N ) {}
};

_Task Cons {
    int N;
    void main() {
        int data;
        for ( int i = 1; i <= N; i += 1 ) {
            while ( ! Insert ) {} // busy wait
            Insert = false;
            data = Data; // remove data
            Remove = true;
        }
    }

    public:
    Cons( int N ) : N( N ) {}
};
```

- 2 infinite loops! No, because of implicit switching of threads.

- cons synchronizes (waits) until prod transfers some data, then prod waits for cons to remove the data.

- A loop waiting for an event among threads is called a **busy wait**.

- Are 2 synchronization flags necessary?

5.13 **Communication**

- Once threads are synchronized there are many ways that information can be transferred from one thread to the other.

- If the threads are in the same memory, then information can be transferred by value or address (e.g., reference parameter).

- If the threads are not in the same memory (distributed), then transferring information by value is straightforward but by address is difficult.
5.14 Critical Section

- Threads may access non-concurrent objects, like a file or linked-list.

- There is a potential problem if there are multiple threads attempting to operate on the same object simultaneously.

- Not a problem if the operation on the object is atomic (not divisible).

- This means no other thread can modify any partial results during the operation on the object (but the thread can be interrupted).

- Where an operation is composed of many instructions, it is often necessary to make the operation atomic.

- A group of instructions on an associated object (data) that must be performed atomically is called a critical section.

- Preventing simultaneous execution of a critical section by multiple threads is called mutual exclusion.

- Must determine when concurrent access is allowed and when it must be prevented.

- One way to handle this is to detect any sharing and serialize all access; wasteful if threads are only reading.

- Improve by differentiating between reading and writing
  - allow multiple readers or a single writer; still wasteful as a writer may only write at the end of its usage.

- Need to minimize the amount of mutual exclusion (i.e., make critical sections as small as possible, Amdahl’s law) to maximize concurrency.

5.15 Static Variables

- Warning: static variables in a class are shared among all objects generated by that class.

- These shared variables may need mutual exclusion for correct usage.

- However, a few special cases where static variables can be used safely, e.g., task constructor.

- If task objects are generated serially, static variables can be used in the constructor.

- E.g., assigning each task is own name:
CHAPTER 5. CONCURRENCE

_Task T {
    static int tid;
    string name; // must supply storage

    public:
    T() {
        name = "T" + itostring( tid ); // shared read
        setName( name.c_str() ); // name task
        tid += 1; // shared write
    }
    ...}

    int T::tid = 0; // initialize static variable in .C file
T t[10]; // 10 tasks with individual names

• Task constructor is executed by the creating thread, so array constructors executed sequentially.

• This approach only works if one task creates all the objects and initialization data is internal.

• Instead of static variables, pass a task identifier to the constructor:

    T::T( int tid ) { ... } // create name
T * t[10]; // 10 pointers to tasks
for ( int i = 0; i < 10; i += 1 ) {
    t[i] = new T(i); // with individual names
}

• In general, it is best to avoid using shared static variables in a concurrent program.

5.16 Mutual Exclusion Game

• Is it possible to write code guaranteeing a statement (or group of statements) is always serially executed by 2 threads?

• Rules of the Game:

    1. Only one thread can be in a critical section at a time with respect to a particular object (safety).
    2. Threads may run at arbitrary speed and in arbitrary order, while the underlying system guarantees a thread makes progress (i.e., threads get some CPU time).
    3. If a thread is not in the entry or exit code controlling access to the critical section, it may not prevent other threads from entering the critical section.
    4. In selecting a thread for entry to a critical section, a selection cannot be postponed indefinitely (liveness). Not satisfying this rule is called indefinite postponement or livelock.
    5. After a thread starts entry to the critical section, it must eventually enter. Not satisfying this rule is called starvation.
• **Indefinite postponement and starvation are related by busy waiting.**

• Unlike synchronization, looping for an event in mutual exclusion *must* ensure eventual progress.

• Threads waiting to enter can be serviced in any order, as long as each thread eventually enters.

• If threads are *not* serviced in first-come first-serve (FCFS) order of arrival, there is a notion of **unfairness**

• Unfairness implies waiting threads are overtaken by arriving threads, called **barging.**

### 5.17 Self-Testing Critical Section

```c
void CriticalSection() {
    static uBaseTask * curr = &uThisTask(); // shared
    for ( int i = 1; i <= 100; i += 1 ) {
        if ( curr != &uThisTask() ) { // check
            abort( "interference" );
        }
        ... // work
    }
}
```

• What is the minimum number of interference tests and where?

• Why are multiple tests useful?

### 5.18 Software Solutions

#### 5.18.1 Lock

```c
enum Yale { CLOSED, OPEN } Lock = OPEN; // shared
_Task PermissionLock {
    void main() {
        for ( int i = 1; i <= 1000; i += 1 ) {
            while ( ::Lock == CLOSED ) {} // entry protocol
            ::Lock = CLOSED;
            CriticalSection(); // critical section
            ::Lock = OPEN; // exit protocol
        }
    }
    public:
        PermissionLock() {}
    }
int main() {
    PermissionLock t0, t1;
}
```

Breaks rule 1
5.18.2 Alternation

```cpp
int Last = 0; // shared
_Task Alternation {
    int me;

    void main() {
        for (int i = 1; i <= 1000; i += 1) {
            while ( ::Last == me ) {} // entry protocol
           CriticalSection(); // critical section
            ::Last = me; // exit protocol
        }
    }
    public:
        Alternation(int me) : me(me) {};
    int main() {
        Alternation t0( 0 ), t1( 1 );
    }
}

Breaks rule 3
```

5.18.3 Declare Intent

```cpp
enum Intent { WantIn, DontWantIn };
_Task DeclIntent {
    Intent & me, & you;
    void main() {
        for (int i = 1; i <= 1000; i += 1) {
            me = WantIn; // entry protocol
            while ( you == WantIn ) {} // critical section
            CriticalSection();
            me = DontWantIn; // exit protocol
        }
    }
    public:
        DeclIntent( Intent & me, Intent & you ) :
            me(me), you(you) {};
    int main() {
        Intent me = DontWantIn, you = DontWantIn;
        DeclIntent t0( me, you ), t1( you, me );
    }
}

Breaks rule 4
```
5.18.4 Retract Intent

```cpp
enum Intent { WantIn, DontWantIn };
_Task RetractIntent {
    Intent & me, & you;
    void main() {
        for ( int i = 1; i <= 1000; i += 1 ) {
            for ( ;; ) {
                // entry protocol
                me = WantIn;
                if ( you == DontWantIn ) break;
                me = DontWantIn;
                while ( you == WantIn ) {}
            }
            CriticalSection();  // critical section
            me = DontWantIn;    // exit protocol
        }
    }
}

public:
    RetractIntent( Intent & me, Intent & you ) : me(me), you(you) {}
};
int main() {
    Intent me = DontWantIn, you = DontWantIn;
    RetractIntent t0( me, you ), t1( you, me );
}

Breaks rule 4
```

5.18.5 Prioritized Retract Intent

```cpp
enum Intent { WantIn, DontWantIn }; enum Priority { HIGH, low };
_Task PriorityEntry {
    Intent & me, & you; Priority priority;
    void main() {
        for ( int i = 1; i <= 1000; i += 1 ) {
            for ( ;; ) {
                // entry protocol
                me = WantIn;
                if ( you == DontWantIn ) break;
                if ( priority == low ) {
                    me = DontWantIn;
                    while ( you == WantIn ) {} // busy wait
                }
            }
            CriticalSection();  // critical section
            me = DontWantIn;    // exit protocol
        }
    }
}

public:
    PriorityEntry( Priority p, Intent & me, Intent & you ) : priority(p), me(me), you(you) {}
};
int main() {
    Intent me = DontWantIn, you = DontWantIn;
    PriorityEntry t0( HIGH, me, you ), t1( low, you, me );
} // main

Breaks rule 5
5.18.6 Dekker (modified retract intent)

```cpp
enum Intent { WantIn, DontWantIn };  
Intent * Last;  
_Task Dekker {  
    Intent & me, & you;  
    void main() {  
        for ( int i = 1; i <= 1000; i += 1 ) {  
            me = WantIn;  
            if ( you == DontWantIn ) break;  
            if ( ::Last == &me ) {  
                me = DontWantIn;  
                while ( ::Last == &me && you == WantIn ) {}  
            }  
        }  
        CriticalSection();  
        if ( ::Last != &me ) // exit protocol  
            ::Last = &me;  
        me = DontWantIn;  
    }  
}  
public:  
    Dekker( Intent & me, Intent & you ) : me(me), you(you) {}  
};  
int main() {  
    Intent me = DontWantIn, you = DontWantIn;  
    ::Last = &me;  
    Dekker t0( me, you ), t1( you, me );  
}
```

- Dekker’s algorithm is not **RW-safe**.

  - RW-safe means a mutual exclusion algorithm works if simultaneous writes scramble bits and simultaneous read/write reads flickering bits.
  - Dekker has no simultaneous W/W because intent reset after alternation in exit protocol.
  - Dekker has simultaneous R/W but all are equality \( \Rightarrow \) final value never flickers.
  - Failure case if final value flickers:
5.18. SOFTWARE SOLUTIONS

T₀
9  ::Last = &me
10  me = DontWantIn
   (flicker DontWantIn)

T₁
3  you == DontWantIn (true)
7  Critical Section
9  ::Last = &me

   (flicker WantIn)

   (flicker DontWantIn)
terminate

6  ::Last == &me (true, spin forever)

• RW-safe version (Hesselink)

  ○ line 6: add conjunction you == WantIn ⇒ stop spinning
  ○ line 8: add conditional assignment to ::Last

T₀
7  Critical Section
9  ::Last = &me
   (flicker you T₀)

   (flicker me T₀)
10  me = DontWantIn
   (repeat)

T₁
6  ::Last == &me && you == WantIn (true)
   (repeat)

  ○ T₁ starvation (rule 5)
  ○ Not assigning at line 9 when ::Last != &me prevents flicker so T₁ makes progress.

• Dekker has unbounded overtaking (not starvation) because race loser retracts intent.

• ⇒ thread exiting critical does not exclude itself for reentry.

  ○ T₀ exits critical section and attempts reentry
  ○ T₁ is now high priority (Last != me) but delays in low-priority busy-loop and resetting its intent.
  ○ T₀ can enter critical section unbounded times until T₁ resets its intent
  ○ T₁ sets intent ⇒ bound of 1 as T₁ can be entering or in critical section

• Unbounded overtaking is allowed by rule 3: not preventing entry to the critical section by the delayed thread.
5.18.7 Peterson (modified declare intent)

```cpp
enum Intent { WantIn, DontWantIn };  
Intent * Last;

_task Peterson
{
  Intent & me, & you;
  void main()
  {
    for( int i = 1; i <= 1000; i += 1 )
    {
      me = WantIn;  // entry protocol, order matters
      ::Last = &me;  // RACE!
      while ( you == WantIn && ::Last == &me ) {}  
      CriticalSection();  // critical section
      me = DontWantIn;  // exit protocol
    }
  }
  public:
    Peterson( Intent & me, Intent & you ) : me(me), you(you) {}
  }

int main()
{
  Intent me = DontWantIn, you = DontWantIn;
  Peterson t0(me, you), t1(you, me);
}
```

- Peterson’s algorithm is RW-unsafe requiring atomic read/write operations.
- Peterson has bounded overtaking because race loser does not retracts intent.
- ⇒ thread exiting critical excludes itself for reentry.
  - T0 exits critical section and attempts reentry
  - T0 runs race by itself and loses
  - T0 must wait (Last == me)
  - T1 eventually sees (Last != me)

- Bounded overtaking is allowed by rule 3 because the prevention is occurring in the entry protocol.
- Can line 2 be moved before 1?

```cpp
 1 2  ::Last = &me;  // RACE!
 2 1  me = WantIn;  // entry protocol
 3 3  while ( you == WantIn && ::Last == &me ) {}  
 4 4  CriticalSection();  // critical section
 5 5  me = DontWantIn;  // exit protocol
```

- T0 executes Line 1 ⇒ ::Last = T0
- T1 executes Line 1 ⇒ ::Last = T1
- T1 executes Line 2 ⇒ T1 = WantIn
- T1 enters CS, because T0 == DontWantIn
- T0 executes Line 2 ⇒ T0 = WantIn
- T0 enters CS, because ::Last == T1
5.18.8 N-Thread Prioritized Entry

```cpp
enum Intent { WantIn, DontWantIn };

Task NTASK { // Burns–Lynch/Lamport: B–L
    Intent * intents; // position & priority
    int N, priority, i, j;
    void main() {
        for (i = 1; i <= 1000; i += 1) {
            // step 1, wait for tasks with higher priority
            do {
                // entry protocol
                intents[priority] = WantIn;
                // check if task with higher priority wants in
                for (j = priority-1; j >= 0; j -= 1) {
                    if (intents[j] == WantIn) {
                        intents[priority] = DontWantIn;
                        while (intents[j] == WantIn) { break; }
                    }
                }
            } while (intents[priority] == DontWantIn);
            // step 2, wait for tasks with lower priority
            for (j = priority+1; j < N; j += 1) {
                while (intents[j] == WantIn) {} }

            CriticalSection();
            intents[priority] = DontWantIn; // exit protocol
        }
    }

    public:
    NTASK( Intent i[], int N, int p ) : intents(i), N(N), priority(p) {} };
```

Breaks rule 5

- Only $N$ bits needed.
• No known solution for all 5 rules using only $N$ bits.

• Other N-thread solutions use more memory.
  (best: 3-bit RW-unsafe, 4-bit RW-safe).

5.18.9 N-Thread Bakery (Tickets)

```c
(Task) Bakery { // (Lamport) Hehner–Shyamasundar
  int * ticket, N, priority;
  void main() {
    for ( int i = 0; i < 1000; i += 1 ) {
      // step 1, select a ticket
      ticket[priority] = 0; // highest priority
      int max = 0; // O(N) search
      for ( int j = 0; j < N; j += 1 ) { // for largest ticket
        int v = ticket[j]; // can change so copy
        if ( v != INT_MAX && max < v ) max = v;
      }
      max += 1; // advance ticket
      ticket[priority] = max;
      // step 2, wait for ticket to be selected
      for ( int j = 0; j < N; j += 1 ) { // check tickets
        while ( ticket[j] < max ||
          (ticket[j] == max && j < priority) ) {}
      }
      CriticalSection();
      ticket[priority] = INT_MAX; // exit protocol
    }
  }
}
```

public:
Bakery( int t[], int N, int p ) : ticket(t), N(N), priority(p) {};
```

<table>
<thead>
<tr>
<th>HIGH priority</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>low priority</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>∞</td>
<td>∞</td>
<td>17</td>
<td>∞</td>
<td>∞</td>
<td>18</td>
<td>18</td>
<td>0</td>
<td>20</td>
<td>19</td>
<td></td>
</tr>
</tbody>
</table>

• ticket value of $\infty$ (INT_MAX) ⇒ don’t want in

• ticket value of 0 ⇒ selecting ticket

• ticket selection is unusual

• tickets are not unique ⇒ use position as secondary priority

• low ticket and position ⇒ high priority

• ticket values cannot increase indefinitely ⇒ could fail (probabilistically correct)

• ticket value reset to INT_MAX when no attempted entry

• $NM$ bits, where $M$ is the ticket size (e.g., 32 bits)
• Lamport RW-safe
• Hehner/Shyamasundar RW-unsafe

assignment ticket[priority] = max can flickers to INT_MAX ⇒ other tasks proceed

5.18.10 Tournament

• Binary (d-ary) tree with \([N/2]\) start nodes and \([\lg N]\) levels.

  \[
  \begin{align*}
  \text{Tournament} & \quad \text{maximal} \\
  T_0 \quad T_1 \quad T_2 \quad T_3 \quad T_4 & \quad D_1 \quad D_2 \quad D_3 \quad D_4 \\
  & \quad \quad D_5 \quad D_6
  \end{align*}
  \]

  \[
  \begin{align*}
  \text{Tournament} & \quad \text{minimal} \\
  T_0 \quad T_1 & \quad D_1 \\
  & \quad D_2 \quad D_3 \quad D_4
  \end{align*}
  \]

• Thread assigned to start node, where it begins mutual exclusion process.
• Each node is like a Dekker or Peterson 2-thread algorithm.
• Tree structure tries to compromise fairness and performance.
• Exit protocol must retract intents in reverse order.
• Otherwise race between retracting/released threads along same tree path:
  • \(T_0\) retracts its intent (left) at \(D_1\),
  • \(T_1\) (right) now moves from \(D_1\) to \(D_4\), sets its intent at \(D_4\) (left), and with no competition at \(D_4\) proceeds to \(D_6\) (left),
  • \(T_0\) (left) now retracts the intent at \(D_4\) set by \(T_1\),
  • \(T_{2/3}\) continue from \(D_2\), sets its intent at \(D_4\) (right), and with no competition at \(D_4\) (left) proceeds to \(D_6\), which ultimately violates mutual exclusion.
• No overall livelock because each node has no livelock.
• No starvation because each node guarantees progress, so each thread eventually reaches the root.
• Tournament algorithm RW-safety depends on MX algorithm; tree traversal is local to each thread.
• Tournament algorithms have unbounded overtaking as no synchronization among the nodes of the tree.
• For a minimal binary tree, the tournament approach uses \((N - 1)M\) bits, where \((N - 1)\) is the number of tree nodes and \(M\) is the node size (e.g., intent, turn).

\[\text{Task} \quad \text{TournamentMax} \quad \{ \quad \text{Taubenfeld–Buhr} \]

\textbf{struct} Token \{ \quad \text{int} \; \text{intents}[2], \text{turn}; \} \quad \text{// intents/turn}

\textbf{static} Token ** t; \quad \text{// triangular matrix}

\textbf{int} \; \text{depth, id;}

\textbf{void} \; \text{main()} \{ \\
\text{unsigned int} \; \text{lid;} \quad \text{// local id at each tree level}
\text{for} \; ( \; \text{int} \; i = 0; \; i < 1000; \; i += 1 \) \{ \\
\text{lid} = \text{id;} \quad \text{// entry protocol}
\text{for} \; ( \; \text{int} \; lv = 0; \; lv < \text{depth}; \; lv += 1 \) \{ \\
\quad \text{binary_prologue}( \; \text{lid} & \; 1, \; \&\&[lv][\text{lid} >> 1] \); \\
\quad \text{lid} >>= 1; \quad \text{// advance local id for next tree level}
\}
\text{CriticalSection( id );}
\text{for} \; ( \; \text{int} \; lv = \text{depth} - 1; \; lv >= 0; \; lv -= 1 \) \{ \text{// exit protocol}
\text{lid} = \text{id} >> \text{lv}; \quad \text{// retract reverse order}
\text{binary_epilogue}( \; \text{lid} & \; 1, \; \&\&[lv][\text{lid} >> 1] \); \\
\}
\}
\textbf{public:}
\text{TournamentMax( \text{struct} \; \text{Token} * \; \text{t}[\;], \; \text{int} \; \text{depth}, \; \text{int} \; \text{id} ) : \\
\text{t( t ), depth( depth ), id( id ) } \} \}

• Can be optimized to 3 shifts and exclusive-or using Peterson 2-thread for binary.

• Path from leaf to root is fixed per thread ⇒ table lookup possible using max or min tree.

5.18.11 Arbiter

• Create full-time arbitrator task to control entry to critical section.

\textbf{bool} \; \text{intents}[N], \; \text{serving}[N]; \quad \text{// initialize to false}

\textbf{Task} \; \text{Client} \{ \\
\text{int} \; \text{me;}
\textbf{void} \; \text{main()} \{ \\
\text{for} \; ( \; \text{int} \; i = 0; \; i < 100; \; i += 1 \) \{ \\
\text{intents}[\text{me}] = \text{true;} \quad \text{// entry protocol}
\textbf{while} \; ( \; ! \; \text{serving}[\text{me}] \; ) \{ \text{// busy wait}
\text{CriticalSection();}
\text{serving}[\text{id}] = \text{false;} \quad \text{// exit protocol}
\}
\}
\textbf{public:}
\text{Client( \; \text{int} \; \text{me} \; ) : me( \; \text{me} \; ) } \}
\}
5.19. HARDWARE SOLUTIONS

- Task Arbiter {
  void main() {
    int i = N;  // force cycle to start at id=0
    for ( ;; ) {
      do {
        i = (i + 1) % N;  // circular search => no starvation
        // advance next client
        while ( ! intents[i] );  // not want in ?
      } while ( ! intents[i] );
      intents[i] = false;  // retract intent on behalf of client
      serving[i] = true;  // wait for exit from critical section
      while ( serving[i] ) {}  // busy wait
    }
  }
};

- Mutual exclusion becomes synchronization between arbiter and clients.
- Arbiter never uses the critical section ⇒ no indefinite postponement.
- Arbiter cycles through waiting clients (not FCFS) ⇒ no starvation.
- RW-unsafe due to read flicker.
- Cost is creation, management, and execution (continuous busy waiting) of arbiter task.

5.19 Hardware Solutions

- Software solutions to the critical-section problem rely on
  - shared information,
  - communication among threads,
  - (maybe) atomic memory-access.
- Hardware solutions introduce level below software level.
- Cheat by making assumptions about execution impossible at software level.
  E.g., control order and speed of execution.
- Allows elimination of much of the shared information and the checking of this information required in the software solution.
- Special instructions to perform an atomic read and write operation.
- Sufficient for multitasking on a single CPU.
5.19.1 Test/Set Instruction

- Simple lock of critical section fails:

```c
int Lock = OPEN;       // shared
// each task does
while ( Lock == CLOSED ); // fails to achieve (read)
Lock = CLOSED;          // mutual exclusion (write)
// critical section
Lock = OPEN;
```

- The test-and-set instruction instruction performs an atomic read and fixed assignment.

```c
int Lock = OPEN;       // shared
int TestSet( int & b ) { // begin atomic
    int temp = b;        // begin atomic
    b = CLOSED;          // begin atomic
    // end atomic
    return temp;
}
```

  - if test/set returns open ⇒ loop stops and lock is set to closed
  - if test/set returns closed ⇒ loop executes until the other thread sets lock to open

- Works for N threads attempting entry to critical section and only depend on one shared datum (lock).

- However, rule 5 is broken, as there is no guarantee of eventual progress.

- In multiple CPU case, hardware (bus) must also guarantee multiple CPUs cannot interleave these special R/W instructions on same memory location.

5.19.2 Swap Instruction

- The swap instruction performs an atomic interchange of two separate values.

```c
int Lock = OPEN;       // shared
void Swap( int & a, & b ) { // begin atomic
    int temp;            // begin atomic
    temp = a;            // begin atomic
    a = b;               // begin atomic
    b = temp;            // begin atomic
    // end atomic
}
```

  - if dummy returns open ⇒ loop stops and lock is set to closed
  - if dummy returns closed ⇒ loop executes until the other thread sets lock to open
5.19. HARDWARE SOLUTIONS

5.19.3 Fetch and Increment Instruction

- The fetch-and-increment instruction performs an increment between the read and write.

```c
int Lock = 0; // shared

int FetchInc( int & val ) { // begin atomic
    int temp = val;
    val += 1;
    // end atomic
    return temp;
}

void Task::main() { // each task does
    while ( FetchInc( Lock ) != 0 );
    // critical section
    Lock = 0;
}
```

- Often fetch-and-increment is generalized to add any value ⇒ also decrement with negative value.

- Lock counter can overflow during busy waiting and starvation (rule 5).

- Use ticket counter to solve both problems (Bakery Algorithm, see Section 5.18.9, p. 88):

```c
class ticketLock {
    unsigned int tickets, serving;

public:
    ticketLock() : tickets( 0 ), serving( 0 ) {} // entry protocol
    void acquire() {
        int ticket = fetchInc( tickets ); // obtain a ticket
        while ( ticket != serving ) {} // busy wait
    }
    void release() { // exit protocol
        serving += 1;
    }
};
```

- Ticket overflow is a problem only if all values used simultaneously, and FIFO service ⇒ no starvation.
6 Locks

- Package software/hardware locking into abstract type for general use.
- Locks are constructed for synchronization or mutual exclusion or both.

6.1 Lock Taxonomy

- Lock implementation is divided into two general categories: spinning and blocking.

\[
\text{spinning} \quad \begin{array}{c|c|c|c|c|c|c}
\text{no yield} & \text{yield} & \text{synchronization} & \text{semaphore} & \text{mutex} & \text{(others)} \\
\hline
\text{condition} & \text{barrier} & \text{binary} & \text{counting} & \text{owner}
\end{array}
\]

- Spinning locks busy wait until an event occurs ⇒ task oscillates between ready and running states due to time slicing.
- Blocking locks do not busy wait, but block until an event occurs ⇒ some other mechanism must unblock waiting task when the event happens.
- Within each category, different kinds of spinning and blocking locks exist.

6.2 Spin Lock

- A spin lock is implemented using busy waiting, which loops checking for an event to occur.

\[
\text{while( TestSet( Lock ) == CLOSED );} \quad \text{// use up time-slice (no yield)}
\]

- So far, when a task is busy waiting, it loops until:
  - critical section becomes unlocked or an event happens.
  - waiting task is preempted (time-slice ends) and put back on ready queue.

Hence, CPU is wasting time constantly checking the event.

- To increase uniprocessor efficiency, a task can:
  - explicitly terminate its time-slice
  - move back to the ready state after only one event-check fails. (Why one?)

- Task member yield relinquish time-slice by rescheduling running task back onto ready queue.

\[
\text{while( TestSet( Lock ) == CLOSED ) \ uThisTask().yield();} \quad \text{// relinquish time-slice}
\]

- To increase multiprocessor efficiency, a task can yield after \( N \) event-checks fail. (Why \( N \)?)
• Some spin-locks allow adjustment of spin duration, called adaptive spin-lock.

• Most spin-lock implementations break rule 5, i.e., no bound on service.
  ⇒ possible starvation of one or more tasks.

• Spin lock is appropriate and necessary in situations where there is no other work to do.

6.2.1 Implementation

• μC++ provides a non-yielding spin lock, uSpinLock, and a yielding spin lock, uLock.

  ```cpp
  class uSpinLock {
  public:
    uSpinLock(); // open
    void acquire();
    bool tryacquire();
    void release();
  }
  
  class uLock {
  public:
    uLock( unsigned int value = 1 );
    void acquire();
    bool tryacquire();
    void release();
  }
  ```

• Both locks are built directly from an atomic hardware instruction.

• Lock starts closed (0) or opened (1); waiting tasks compete to acquire lock after release.

• In theory, starvation could occur; in practice, it is seldom a problem.

• tryacquire makes one attempt to acquire the lock, i.e., it does not wait.

• It is not meaningful to read or to assign to a lock variable, or copy a lock variable, e.g., pass it as a value parameter.

• synchronization

  ```cpp
  _Task T1 {
    uLock & lk;
    void main() {
      ... 
      lk.release();
      ...
    }
    public:
    T1( uLock & lk ) : lk(lk) {} 
  }

  _Task T2 {
    uLock & lk;
    void main() {
      ... 
      lk.acquire();
      S2
      ...
    }
    public:
    T2( uLock & lk ) : lk(lk) {} 
  }
  ```

• mutual exclusion
6.3 Blocking Locks

- For spinning locks,
  - acquiring task(s) is solely responsible for detecting an open lock after the releasing task opens it.

- For blocking locks,
  - acquiring task makes one check for open lock and blocks
  - releasing task has sole responsibility for detecting blocked acquirer and transferring lock, or just releasing lock.

- Blocking locks reduce busy waiting by having releasing task do additional work: cooperation.

  - What advantage does the releasing task get from doing the cooperation?

- Therefore, all blocking locks have
  - state to facilitate lock semantics
  - list of blocked acquirers

- Which task is scheduled next from the list of blocked tasks?
6.3.1 Mutex Lock

- **Mutex lock** is used solely to provide mutual exclusion.

- Restricting a lock to just mutual exclusion:
  - separates lock usage between synchronization and mutual exclusion
  - permits optimizations and checks as the lock only provides one specialized function

- Mutex locks are divided into two kinds:
  - **single acquisition**: task that acquired the lock cannot acquire it again
  - **multiple acquisition**: lock owner can acquire it multiple times, called an **owner lock**

- Multiple acquisition can handle looping or recursion involving a lock:

  ```
  void f() {
      ...
      lock.acquire();
      ... f();       // recursive call within critical section
      lock.release();
  }
  ```

- May require only one release to unlock, or as many releases as acquires.

6.3.1.1 Implementation

- Multiple acquisition lock manages owner state.

```
class MutexLock {
    queue<Task> blocked; // blocked tasks
    bool avail; // resource available ?
    Task * owner // lock owner
    SpinLock lock; // mutex nonblocking lock

public:
    MutexLock() : avail( true ), owner( nullptr ) {} 
    void acquire() {
        lock.acquire(); // barging
        while ( ! avail && owner != currThread() ) { // busy waiting
            // add self to lock's blocked list
            yieldNoSchedule(); // do not reschedule to ready queue
            lock.acquire(); // reacquire spinlock
        }
        avail = false;
        owner = currThread(); // set new owner
        lock.release();
    }
}
```
void release() {
    lock.acquire();
    if ( owner != currThread() ) ... // ERROR CHECK
    owner = nullptr; // no owner
    if ( ! blocked.empty() ) {
        // remove task from blocked list and make ready
    }
    avail = true; // reset
    lock.release(); // RACE
}

• yieldNoSchedule yields the processor time-slice but does not reschedule thread to ready queue.

• Single or multiple unblock for multiple acquisition?

• avail is necessary as queue can be empty but critical section occupied.

• Problem: blocking occurs holding lock!

• ⇒ release lock before blocking

    // add self to blocked list of lock
    lock.release(); // allow releasing task to unblock next waiting task
    // PREEMPTION ⇒ put on ready queue
    yieldNoSchedule();

• Race between blocking and unblocking tasks.

• Blocking task releases spin lock but preempted before yield and put onto ready queue.

• Unblocking task can enter, see blocking task on lock’s blocked list, and put on ready queue.

• But task is already on the ready queue because of the preemption!

• Need magic to atomically yield without scheduling and release spin lock.

• Magic is often accomplished with more cooperation:

    yieldNoSchedule( lock );

• Spin lock is passed to the runtime system, which does the yield without schedule and then, on behalf of the user, unlocks the lock.

• Note, the runtime system violates order and speed of execution by being non-preemptable.

• Problem: avail and lock reset ⇒ acquiring tasks can barge ahead of released task.

• Released task must check again (while) ⇒ busy waiting
• **Barging avoidance** (cooperation): hold avail between releasing and unblocking task (bounded overtaking)

```c
void acquire() {
    lock.acquire(); // barging
    if ( ! avail && owner != currThread() ) { // avoid barging
        // add self to lock's blocked list
        yieldNoSchedule( lock );
        lock.acquire(); // reacquire spinlock
    }
    avail = false;
    owner = currThread(); // set new owner
    lock.release();
}
```

```c
void release() {
    lock.acquire();
    owner = nullptr; // no owner
    if ( ! blocked.empty() ) {
        // remove task from blocked list and make ready
    } else {
        avail = true; // conditional reset
    }
    lock.release(); // RACE
}
```

• Bargers enter mutual-exclusion protocol but block so released task does not busy wait (if rather than while).

• **Continuous barging** ⇒ starvation as released task waits to reacquire spin lock.

• **Barging prevention** (cooperation): hold lock between releasing and unblocking task

```c
void acquire() {
    lock.acquire(); // prevention barging
    if ( ! avail && owner != currThread() ) {
        // add self to lock's blocked list
        yieldNoSchedule( lock );
        // DO NOT REACQUIRE LOCK
    }
    avail = false;
    owner = currThread(); // set new owner
    lock.release();
}
```
6.3. BLOCKING LOCKS

void release() {
    lock.acquire();
    owner = nullptr;     // no owner
    if ( ! blocked.empty() ) {
        // remove task from blocked list and make ready
        // DO NOT RELEASE LOCK
    } else {
        avail = true;       // conditional reset
        lock.release();     // NO RACE
    }
}

• Spin lock is \textit{conceptually passed} from releasing to unblocking tasks (baton passing).

• Bargers cannot enter ⇒ no starvation as released task does not require lock.

• \textbf{Critical section is not bracketed by the spin lock when lock is passed.}

• Alternative (cooperation): leave lock owner at front of blocked list to act as availability and owner variable.

class MutexLock {
    queue<Task> blocked;     // blocked tasks
    SpinLock lock;           // nonblocking lock
public:
    void acquire() {
        lock.acquire();      // prevention barging
        if ( blocked.empty() ) {
            // no one waiting ?
            node.owner = currThread();
            // add self to lock's blocked list
        } else if ( blocked.head().owner != currThread() ) {
            // not owner ?
            // add self to lock's blocked list
            yieldNoSchedule( lock );
            // DO NOT REACQUIRE LOCK
        }
        lock.release();
    }

    void release() {
        lock.acquire();
        // REMOVE TASK FROM HEAD OF BLOCKED LIST
        if ( ! blocked.empty() ) {
            // MAKE TASK AT FRONT READY BUT DO NOT REMOVE
            // DO NOT RELEASE LOCK
        } else {
            lock.release();     // NO RACE
        }
    }
};

• If critical section acquired, blocked list must have a node on it to check for in-use.
6.3.1.2 uOwnerLock

- \(\mu\text{C}++\) provides a multiple-acquisition mutex-lock, uOwnerLock:

```cpp
class uOwnerLock {
public:
    uOwnerLock();
    uBaseTask *owner();
    unsigned int times();
    void acquire();
    bool tryacquire();
    void release();
};
```

- \texttt{owner()} returns \texttt{nullptr} if no owner, otherwise address of task that currently owns lock.
- \texttt{times()} returns number of times lock has been acquired by owner task.
- Must release as many times as acquire.
- Otherwise, operations same as for uLock but with blocking instead of spinning for acquire.

6.3.1.3 Mutex-Lock Release-Pattern

- To ensure a mutual exclusion lock is always released use the following patterns.
  - executable statement – finally clause
    ```cpp
    uOwnerLock lock;
    lock.acquire();
    try {
        ... // protected by lock
    } _Finally {
        lock.release();
    }
    ```
  - allocation/deallocation (RAII – Resource Acquisition Is Initialization)
    ```cpp
class RAII { // create once
    uOwnerLock & lock;
public:
    RAII( uOwnerLock & lock ) : lock( lock ) { lock.acquire(); }
    ~RAII() { lock.release(); }
};
```
    ```cpp
    uOwnerLock lock;
    {
        RAII raii( lock ); // lock acquired by constructor
        ... // protected by lock
        // lock release by destructor
    }
    ```
- Lock always released on normal, local transfer (\texttt{break/return}), and exception.
6.3. BLOCKING LOCKS

6.3.1.4 Stream Locks

- Specialized mutex lock for I/O based on uOwnerLock.
- Concurrent use of C++ streams can produce unpredictable results.
  - if two tasks execute:
    
    ```
    task1: cout << "abc " << "def " << endl;
    task2: cout << "uvw " << "xyz " << endl;
    ```

    any of the outputs can appear:

    | abc def | abc uvw xyz | uvw abc xyz def | abuvwc dexf | uvw abc def |
    | uvw xyz | def          | yz             | xyz          |

- µC++ provides: osacquire for output streams and isacquire for input streams.
- Most common usage is to create as anonymous stream lock for a cascaded I/O expression:
  
  ```
  task1: osacquire( cout ) << "abc " << "def " << endl;
  task2: osacquire( cout ) << "uvw " << "xyz " << endl;
  ```

  constraining the output to two different lines in either order:

  | abc def | uvw xyz |
  | uvw xyz | abc def |

- Multiple I/O statements can be protected using block structure:

  ```
  { // acquire the lock for stream cout for block duration
    osacquire acq( cout ); // named stream lock
    cout << "abc";
    osacquire( cout ) << "uvw " << "xyz " << endl; // OK?
    cout << "def";
  } // implicitly release the lock when “acq” is deallocated
  ```

- Which locking-release pattern is used by stream locks?

6.3.2 Synchronization Lock

- **Synchronization lock** is used solely to block tasks waiting for synchronization.
- Weakest form of blocking lock as its only state is list of blocked tasks.
  - ⇒ **acquiring task always blocks** (no state to make it conditional)
    
    Need ability to yield time-slice and block versus yield and go back on ready queue.
  - ⇒ **release is lost when no waiting task** (no state to remember it)
- Often called a **condition lock**, with wait / signal(notify) for acquire / release.
6.3.2.1 Implementation

- Like mutex lock, synchronization lock needs mutual exclusion for safe implementation.

- Location of mutual exclusion classifies synchronization lock:

  **external locking** use an external lock to protect task list,

  **internal locking** use an internal lock to protect state (lock is extra state).

- external locking

  ```cpp
  class SyncLock {
    Task * list;
  public:
    SyncLock() : list( nullptr ) {}  
    void acquire() {
      // add self to task list
      yieldNoSchedule();
    }
    void release() {
      if ( list != nullptr ) {
        // remove task from blocked list and make ready
      }
    }
  };
  ```

  - Use external state to avoid lost release.
  - Need mutual exclusion to protect task list and possible external state.
  - Releasing task detects a blocked task and performs necessary cooperation.

- Usage pattern:

  - Cannot enter a restaurant if all tables are full.
  - Must acquire a lock to check for an empty table because state can change.
  - If no free table, block on waiting-list until a table becomes available.
6.3. BLOCKING LOCKS

// shared variables
MutexLock m; // external mutex lock
SyncLock s; // synchronization lock
bool occupied = false; // indicate if event has occurred

// acquiring task
m.acquire(); // mutual exclusion to examine state & possibly block
if (occupied) {
    s.acquire(); // long-term block for event
    m.acquire(); // require mutual exclusion to set state
}
occupied = true; // set
m.release();

... eat ...

// releasing task
m.acquire(); // mutual exclusion to examine state
occupied = false; // reset
s.release(); // possibly unblock waiting task
m.release(); // release mutual exclusion

• Blocking occurs holding external mutual-exclusion lock!

• ⇒ release lock before blocking

    // acquiring task
    m.acquire(); // mutual exclusion to examine state & possibly block
    if (occupied) {
        m.release(); // release external mutex–lock
        // PREEMPTION
        s.acquire(); // block for event
        ...

    • Race between blocking and unblocking tasks.
• To prevent race, modify synchronization-lock acquire to release lock.

```c
void acquire( MutexLock & m ) {
    // add self to task list
    yieldNoSchedule( m );  // possibly reacquire mutex
}
```

• Or, protecting mutex-lock is bound at synchronization-lock creation and used implicitly.

• Now use first usage pattern.

```c
// acquiring task
m.acquire();  // mutual exclusion to examine state & possibly block
if ( occupied ) {
    s.acquire( m );  // block for event and release mutex lock
    ...
}
```

• Has the race been prevented?

• internal locking

```c
class SyncLock {
    Task * list;  // blocked tasks
    SpinLock lock;  // internal lock
    public:
    SyncLock() : list( nullptr ) {}  
    void acquire( MutexLock & m ) {  // optional external lock
        lock.acquire();  // add self to task list
        m.release();  // release external mutex–lock
        CAN BE INTERRUPTED HERE
        yieldNoSchedule( lock );
        m.acquire();  // possibly reacquire after blocking
    }
    void release() {
        lock.acquire();
        if ( list != nullptr ) {
            // remove task from blocked list and make ready
        }
        lock.release();
    }
};
```

◦ Why does acquire still take an external lock?

◦ Why is the race after releasing the external mutex-lock not a problem?

• Has the busy wait been removed from the blocking lock?
6.3. **BLOCKING LOCKS**

### 6.3.2.2 uCondLock

- μC++ provides an internal synchronization-lock, uCondLock.

```cpp
class uCondLock {
    public:
        uCondLock();
        void wait( uOwnerLock & lock );
        bool signal();
        bool broadcast();
        bool empty();
};
```

- `wait` and `signal` are used to block a thread on and unblock a thread from the queue of a condition, respectively.

- `wait` atomically blocks the calling task and **releases argument owner-lock**.

- **wait reacquires its argument owner-lock before returning.**

- `signal` unblocks a single task in FIFO order.

- `broadcast` unblocks all waiting tasks.

- `signal/broadcast` do nothing for an empty condition and return false; otherwise, return true.

- `empty` returns **false** if blocked tasks on the queue and **true** otherwise.

### 6.3.2.3 Programming Pattern

- Using synchronization locks is complex because they are weak.

- Must provide external mutual-exclusion and protect against loss signal (release).

- Why is synchronization more complex for blocking locks than spinning (uLock)?
bool done = false;

_Task T1 {
    uOwnerLock & mlk;
    uCondLock & clk;

    void main() {
        mlk.acquire(); // prevent lost signal
        if ( ! done ) // signal occurred ?
            clk.wait( mlk ); // atomic wait/release
        mlk.release(); // release either way
    }

    public:
    T1( uOwnerLock & mlk, uCondLock & clk ) :
        mlk(mlk), clk(clk) {} 
};

int main() {
    uOwnerLock mlk;
    uCondLock clk;
    T1 t1( mlk, clk );
    T2 t2( mlk, clk );
}

_Task T2 {
    uOwnerLock & mlk;
    uCondLock & clk;

    void main() {
        S1;
        mlk.acquire(); // prevent lost signal
        done = true; // remember signal occurred
        clk.signal(); // signal if not waiting
        mlk.release();
    }

    public:
    T2( uOwnerLock & mlk, uCondLock & clk ) :
        mlk(mlk), clk(clk) {} 
};

6.3.3 Barrier

- A barrier coordinates a group of tasks performing a concurrent operation surrounded by sequential operations.

- Hence, a barrier is for synchronization and cannot build mutual exclusion.

- Unlike previous synchronization locks, a barrier retains state about the events it manages: number of tasks blocked on the barrier.

- Since manipulation of this state requires mutual exclusion, most barriers use internal locking.

- E.g., 3 tasks must execute a section of code in a particular order: S1, S2 and S3 must all execute before S5, S6 and S7.
6.3. **BLOCKING LOCKS**

```c
T1::main() {
    . . .
    S1
    b.block();
    S5
    . . .
}

T2::main() {
    . . .
    S2
    b.block();
    S6
    . . .
}

T3::main() {
    . . .
    S3
    b.block();
    S7
    . . .
}

int main() {
    Barrier b( 3 );
    T1 x( b );
    T2 y( b );
    T3 z( b );
}
```

- Barrier is initialized to control 3 tasks and passed to each task by reference (not copied).
- Barrier blocks each task at call to `block` until all tasks have called `block`.
- Last task to call `block` does not block and releases other tasks (cooperation).
- Hence, all tasks leave together (synchronized) after arriving at the barrier.
- Note, must specify in advance total number of `block` operations before tasks released.
- Two common uses for barriers:

```
Barrier start(N+1), end(N+1); // shared
Coordinator
// start N tasks so they can initialize
// general initialization
start.block(); // wait for threads to start
// do other work
end.block(); // wait for threads to end
// general close down and possibly loop
```

```
Workers
// initialize
start.block(); // wait for threads to start
// do work
end.block(); // wait for threads to end
// close down
```

- Two barriers allow Coordinator to accumulate results (subtotals) while Workers reinitialize (read next row).
- Alternative is last Worker does coordination, but prevents Workers reinitializing during coordination.
- Why not use termination synchronization and create new tasks for each computation?
  - creation and deletion of computation tasks is expensive
6.3.3.1 uBarrier

- µC++ barrier is a thread-safe coroutine, where the coroutine main can be resumed by the last task arriving at the barrier.

```cpp
#include <uBarrier.h>
_Cormonitor uBarrier { // think _Coroutine
    protected:
        void main() { for (;;) suspend(); } // points of synchronization
        virtual void last() { resume(); } // called by last task to barrier
    public:
        uBarrier( unsigned int total );
        unsigned int total() const; // # of tasks synchronizing
        unsigned int waiters() const; // # of waiting tasks
        void reset( unsigned int total ); // reset # tasks synchronizing
        virtual void block(); // wait for Nth thread, Nth thread unblocks & calls last
};
```

- uBarrier has implicit mutual exclusion ⇒ no barging ⇒ only manage synchronization

- User barrier is built by:
  - inheriting from uBarrier
  - redefining last and/or block member and possibly coroutine main
  - possibly initializing main from constructor

- E.g., previous matrix sum (see page 75) adds subtotals in order of task termination, but barrier can add subtotals in order produced.

```cpp
_Cormonitor Accumulator : public uBarrier {
    int total_ = 0, temp;
    uBaseTask * Nth_ = nullptr;
    protected:
        void last() { // reset and remember Nth task
            temp = total_; total_ = 0;
            Nth_ = &uThisTask();
        }
    public:
        Accumulator( int rows ) : uBarrier( rows ) {}
        void block( int subtotal ) {
            total_ += subtotal;
            uBarrier::block();
        }
        int total() { return temp; }
        uBaseTask * Nth() { return Nth_; }
};
```
6.3. BLOCKING LOCKS

_Task_ Adder {
    int * row, size;
    Accumulator & acc;
    void main() {
        int subtotal = 0;
        for ( unsigned int r = 0; r < size; r += 1 ) subtotal += row[r];
        acc.block( subtotal ); // provide subtotal; block for completion
    }
}

public:
    Adder( int row[], int size, Accumulator & acc ) :
        size( size ), row( row ), acc( acc ) {}
};

int main() {
    enum { rows = 10, cols = 10};
    int matrix[rows][cols];
    Adder * adders[rows];
    Accumulator acc( rows ); // barrier synchronizes each summation
    // read matrix
    for ( unsigned int r = 0; r < rows; r += 1 )
        adders[r] = new Adder( matrix[r], cols, acc );
    for ( unsigned int r = 0; r < rows; r += 1 )
        delete adders[r];
    cout << acc.total() << " " << acc.Nth() << endl;
}

• Why not have task delete itself after unblocking from _uBarrier::block_()?

    void block( int subtotal ) { total_ += subtotal; _uBarrier::block();
        delete &uThisTask(); }

• Coroutine barrier can be reused many times, e.g., read in a new matrix in Accumulator::main
after each summation.

6.3.4 Binary Semaphore

• Binary semaphore (Edsger W. Dijkstra) is blocking equivalent to yielding spin-lock.

• Provides synchronization and mutual exclusion.

    Semaphore lock(0); // 0 => closed, 1 => open, default 1

• More powerful than synchronization lock as it remembers state about an event.

• Names for acquire and release from Dutch terms

• acquire is P

    o passeren ⇒ to pass
    o prolagen ⇒ (proberen) to try (verlagen) to decrease
lock.P(); // wait to enter

P waits if the semaphore counter is zero and then decrements it.

- release is V
  - vrijgeven ⇒ to release
  - verhogen ⇒ to increase

lock.V(); // release lock

V increases the counter and unblocks a waiting task (if present).

- When the semaphore has only two states (open/closed), it is called a binary semaphore.

- synchronization

  _Task T1 {
    BinSem & lk;
    void main() {
      ...
      S1
      lk.V();
      ...
    }
    public:
    T1( BinSem & lk ) : lk(lk) {}
  }

  int main() {
    BinSem lock( 0 ); // closed
    T1 t1( lock );
    T2 t2( lock );
  }

- mutual exclusion

  _Task T {
    BinSem & lk;
    void main() {
      ...
      lk.P();
      // critical section
      lk.V();
      ...
      lk.P();
      // critical section
      lk.V();
      ...
    }
    public:
    T( BinSem & lk ) : lk(lk) {}
  }

  int main() {
    BinSem lock( 1 ); // start open
    T t0( lock ), t1( lock );
  }
6.3. BLOCKING LOCKS

6.3.4.1 Implementation

- Implementation has:
  - blocking task-list
  - avail indicates if event has occurred (state)
  - spin lock to protect state

```cpp
class BinSem {
    queue<Task> blocked; // blocked tasks
    bool avail; // resource available?
    SpinLock lock; // mutex nonblocking lock

public:
    BinSem( bool start = true ) : avail( start ) {}
    void P() {
        lock.acquire(); // prevention barging
        if ( ! avail ) {
            // add self to lock's blocked list
            yieldNoSchedule( lock );
            // DO NOT REACQUIRE LOCK
        }
        avail = false;
        lock.release();
    }
    void V() {
        lock.acquire();
        if ( ! blocked.empty() ) {
            // remove task from blocked list and make ready
            // DO NOT RELEASE LOCK
        } else {
            avail = true; // conditional reset
            lock.release(); // NO RACE
        }
    }
};
```

- Same as single-acquisition mutexLock but can initialize avail.
- Higher cost for synchronization if external lock already acquired.

6.3.5 Counting Semaphore

- Augment the definition of P and V to allow a multi-valued semaphore.
- What does it mean for a lock to have more than open/closed (unlocked/locked)?
  - $\Rightarrow$ critical sections allowing $N$ simultaneous tasks.
- Augment V to allow increasing the counter an arbitrary amount.
- synchronization
Three tasks must execute so S2 and S3 only execute after S1 has completed.

```cpp
T1::main() {
    ... lk.P(); S2; ... lk.V(); ...
} T2::main() {
    ... lk.P(); S3; ... lk.V(); ...
} T3::main() {
    ... S1; ... lk.V(); ...
}
```

```cpp
int main() {
    CntSem lock( 0 ); // closed
    T1 x( lock );
    T2 y( lock );
    T3 z( lock );
}
```

- mutual exclusion

- Critical section allowing up to 3 simultaneous tasks.

```cpp
Task T {
    CntSem & lk;
    void main() {
        ... lk.P();
        // up to 3 tasks in
        // critical section
        lk.V();
        ...
    }

    public:
    T( BinSem & lk ) : lk(lk) {}
};
```

```cpp
int main() {
    CntSem lock( 3 ); // allow 3
    T t0( lock ), t1( lock ), ...;
}
```

- Must know in advance the total number of P’s on the semaphore.

6.3.5.1 Implementation

- Change availability into counter, and set to some maximum on creation.

- Decrement counter on acquire and increment on release.

- Block acquiring task when counter is 0.

- Negative counter indicates number of waiting tasks.
class CntSem {
    queue<Task> blocked; // blocked tasks
    int cnt; // resource being used?
    SpinLock lock; // nonblocking lock
public:
    CntSem( int start = 1 ) : cnt( start ) {} 
    void P() {
        lock.acquire();
        cnt -= 1;
        if ( cnt < 0 ) {
            // add self to lock's blocked list
            yieldNoSchedule( lock );
            // DO NOT REACQUIRE LOCK
        }
        lock.release();
    }
    void V() {
        lock.acquire();
        cnt += 1;
        if ( cnt <= 0 ) {
            // remove task from blocked list and make ready
            // DO NOT RELEASE LOCK
        } else {
            lock.release(); // NO RACE
        }
    }
};

• In general, binary/counting semaphores are used in two distinct ways:

1. For synchronization, if the semaphore starts at 0 ⇒ waiting for an event to occur.
2. For mutual exclusion, if the semaphore starts at 1(N) ⇒ controls a critical section.

• µC++ provides a counting semaphore, uSemaphore, which subsumes a binary semaphore.

#include <uSemaphore.h>
class uSemaphore {
public:
    uSemaphore( unsigned int count = 1 );
    void P();
    bool TryP();
    void V( unsigned int times = 1 );
    int counter() const;
    bool empty() const;
};

• P decrements the semaphore counter; if the counter is greater than or equal to zero, the calling task continues, otherwise it blocks.

• TryP returns true if the semaphore is acquired and false otherwise (never blocks).
• **V** wakes up the task blocked for the longest time if there are tasks blocked on the semaphore and increments the semaphore counter.

• If **V** is passed a positive integer N, the semaphore is **V**ed N times.

• The member routine **counter** returns the value of the semaphore counter:
  - negative means \(\text{abs}(N)\) tasks are blocked waiting to acquire the semaphore, and the semaphore is locked;
  - zero means no tasks are waiting to acquire the semaphore, and the semaphore is locked;
  - positive means the semaphore is unlocked and allows \(N\) tasks to acquire the semaphore.

• The member routine **empty** returns **false** if there are threads blocked on the semaphore and **true** otherwise.

### 6.4 Lock Programming

#### 6.4.1 Precedence Graph

• **P** and **V** in conjunction with **COBEGIN** are as powerful as **START** and **WAIT**.

• E.g., execute statements so the result is the same as serial execution but concurrency is maximized.

  \[
  \begin{align*}
  S1: & \quad a := 1 \\
  S2: & \quad b := 2 \\
  S3: & \quad c := a + b \\
  S4: & \quad d := 2 \cdot a \\
  S5: & \quad e := c + d
  \end{align*}
  \]

• Analyse which data and code depend on each other.

• I.e., statement **S1** and **S2** are independent ⇒ can execute in either order or at the same time.

• Statement **S3** is dependent on **S1** and **S2** because it uses both results.

• Display dependences graphically in a **precedence graph** (different from process graph).
6.4. LOCK PROGRAMMING

Semaphore L1(0), L2(0), L3(0), L4(0);
COBEGIN
BEGIN a := 1; V(L1); END;
BEGIN b := 2; V(L2); END;
BEGIN P(L1); P(L2); c := a + b; V(L3); END;
BEGIN P(L1); d := 2 * a; V(L4); END;
BEGIN P(L3); P(L4); e := c + d; END;
COEND

• Does this solution work?

• Optimal solution: minimum threads, M, and traverse M paths through precedence graph.

Semaphore L1(0), L2(0);
COBEGIN
BEGIN a := 1; V(L1); d := 2 * a; V(L2);
BEGIN b := 2; P(L1); c := a + b; P(L2); e := c + d; END;
COEND

• process graph (different from precedence graph)

6.4.2 Buffering

• Tasks communicate unidirectionally through a queue.

• Producer adds items to the back of a queue.

• Consumer removes items from the front of a queue.
### 6.4.2.1 Unbounded Buffer

- Two tasks communicate through a queue of unbounded length.

```
producer   • • •   consumer
```

- Because tasks work at different speeds, producer may get ahead of consumer.
  - Producer never has to wait as buffer has infinite length.
  - Consumer has to wait if buffer is empty ⇒ wait for producer to add.

- Queue is shared between producer/consumer, and counting semaphore controls access.

```c
#define QueueSize ∞
int front = 0, back = 0;
int Elements[QueueSize];
uSemaphore full(0);

void Producer::main() {
    for (;;) {
        // produce an item
        // add to back of queue
        full.V();
    }
    // produce a stopping value
    // . . .
}

void Consumer::main() {
    for (;;) {
        full.P();
        // take an item from the front of the queue
        if (stopping value ?) break;
        // process or consume the item
    }
}
```

- Is there a problem adding and removing items from the shared queue?
- Is the `full` semaphore used for mutual exclusion or synchronization?

### 6.4.2.2 Bounded Buffer

- Two tasks communicate through a queue of bounded length.

- Because of bounded length:
  - Producer has to wait if buffer is full ⇒ wait for consumer to remove.
  - Consumer has to wait if buffer is empty ⇒ wait for producer to add.
6.4. LOCK PROGRAMMING

• Use counting semaphores to account for the finite length of the shared queue.

```c
uSemaphore full(0), empty(QueueSize);
void Producer::main() {
    for ( ;; ) {
        // produce an item
        empty.P();
        // add element to buffer
        full.V();
    }
    // produce a stopping value
}
void Consumer::main() {
    for ( ;; ) {
        full.P();
        // remove element from buffer
        if (stopping value?) break;
        // process or consume the item
        empty.V();
    }
}
```

• Does this produce maximum concurrency?

• Can it handle multiple producers/consumers?

<table>

6.4.3 Lock Techniques

• Many possible solutions; need systematic approach.

• A split binary semaphore is a collection of semaphores where at most one of the collection has the value 1.
  
  ○ I.e., the sum of the semaphores is always less than or equal to one.
  ○ Used when different kinds of tasks have to block separately.
  ○ Cannot differentiate tasks blocked on the same semaphore (condition) lock. Why?
- E.g., A and B tasks block on different semaphores so they can be unblocked based on kind, but collectively manage 2 semaphores like it was one.

- Split binary semaphores can be used to solve complicated mutual-exclusion problems by a technique called **baton passing**.

- The rules of baton passing are:
  - there is exactly one (conceptual) baton
  - nobody moves in the entry/exit code unless they have it
  - once the baton is released, cannot read/write variables in entry/exit

- E.g., baton is conceptually acquired in entry/exit protocol and passed from signaller to signalled task (see page 101).

```cpp
class BinSem {
    queue<Task> blocked;
    bool avail;
    SpinLock lock;
public:
    BinSem( bool start = true ) : avail( start ) {}
    void P() {
        lock.acquire(); /* PICKUP BATON, CAN ACCESS STATE */
        if ( ! avail ) {
            // add self to lock's blocked list
            /* PUT DOWN BATON, CANNOT ACCESS STATE */
            yieldNoSchedule( lock );
            // UNBLOCK WITH SPIN LOCK ACQUIRED
            /* PASSED BATON, CAN ACCESS STATE */
        }
        avail = false;
        lock.release(); /* PUT DOWN BATON, CANNOT ACCESS STATE */
    }

    void V() {
        lock.acquire(); /* PICKUP BATON, CAN ACCESS STATE */
        if ( ! blocked.empty() ) {
            // remove task from blocked list and make ready
            /* PASS BATON, CANNOT ACCESS STATE */
        } else {
            avail = true;
            lock.release(); /* PUT DOWN BATON, CANNOT ACCESS STATE */
        }
    }
};
```

- Can mutex/condition lock perform baton passing to prevent barging?
  - Not if signalled task must implicitly re-acquire the mutex lock before continuing.
  - ⇒ signaller must release the mutex lock.
  - There is now a race between signalled and calling tasks, resulting in barging.
6.4.4 Readers and Writer Problem

- Multiple tasks sharing a resource: some reading the resource and some writing the resource.
- Allow multiple concurrent reader tasks simultaneous access, but serialize access for writer tasks (a writer may read).
- Use split-binary semaphore to segregate 3 kinds of tasks: arrivers, readers, writers.
- Use baton-passing to help understand complexity.

6.4.4.1 Solution 1

```cpp
uSemaphore entry(1), rwait(0), wwait(0); // split binary semaphores
int rdel = 0, wdel = 0, rcnt = 0, wcnt = 0; // auxiliary counters
void Reader::main() {
    entry.P(); // pickup baton
    if ( wcnt > 0 ) {
        rdel += 1; entry.V(); // put baton down
        rwait.P(); rdel -= 1; // passed baton
    }
    rcnt += 1;
    if ( rdel > 0 ) { // waiting readers ?
        rwait.V(); // pass baton
    } else {
        entry.V(); // put baton down
    }

    // READ
    entry.P(); // pickup baton
    rcnt -= 1;
    if ( rcnt == 0 && wdel > 0 ) { // waiting writers ?
        wwait.V(); // pass baton
    } else {
        entry.V(); // put baton down
    }
}
```
void Writer::main() {
    entry.P(); // pickup baton
    if ( rcnt > 0 || wcnt > 0 ) {
        wdel += 1; entry.V(); // put baton down
        wwait.P(); wdel -= 1; // passed baton
    }
    wcnt += 1;
    entry.V(); // put baton down
    // WRITE
    entry.P(); // pickup baton
    wcnt -= 1;
    if ( rdel > 0 ) {
        rdel += 1; entry.V(); // put baton down
        rwait.P(); rdel -= 1; // passed baton
    }
    else if ( wdel > 0 ) {
        wwait.V(); // pass baton
    }
    else {
        entry.V(); // put baton down
    }
}

- Problem: reader only checks for writer in resource, never writers waiting to use it.
  - ⇒ readers barge ahead of writers who already waited.
  - ⇒ continuous stream of readers (actually only 2 needed) prevent waiting writers from making progress (starvation).

### 6.4.4.2 Solution 2

- Give writers priority and make the readers wait.
  - Works most of the time because normally 80% readers and 20% writers.

- Change entry protocol for reader to the following:

```cpp
entry.P(); // pickup baton
if ( wcnt > 0 || wdel > 0 ) {
    rdel += 1; entry.V(); // put baton down
    rwait.P(); rdel -= 1; // passed baton
}
rcnt += 1;
if ( rdel > 0 ) {
    rwait.V(); // pass baton
}
else {
    entry.V(); // put baton down
}
```

- Also, change writer’s exit protocol to favour writers:
entry.P(); // pickup baton
wcnt -= 1;
if ( wdel > 0 ) { // check writers first
wwait.V(); // pass baton
} else if ( rdel > 0 ) {
rwait.V(); // pass baton
} else {
entry.V(); // put baton down
}

○ ⇒ writers barge.
○ ⇒ continuous stream of writers cause reader starvation.

6.4.4.3 Solution 3

• Fairness on simultaneous arrival is solved by alternation (Dekker’s solution).

• E.g., use last flag to indicate the kind of tasks last using the resource, i.e., reader or writer.

• On exit, first select from opposite kind, e.g., if last is reader, first check for waiting writer otherwise waiting reader, then update last.

• Flag is unnecessary if readers wait when there is a waiting writer, and all readers started after a writer.

• ⇒ put writer’s exit-protocol back to favour readers.

entry.P(); // pickup baton
wcnt -= 1;
if ( rdel > 0 ) { // check readers first
rwait.V(); // pass baton
} else if ( wdel > 0 ) {
wwait.V(); // pass baton
} else {
entry.V(); // put baton down
}

• Arriving readers cannot barge ahead of waiting writers and unblocking writers cannot barge ahead of a waiting reader

• ⇒ alternation for simultaneous waiting.

6.4.4.4 Solution 4

• Problem: temporal barging!

• Staleness/freshness for last flag and staleness with no-flag.
• Alternation for simultaneous waiting means when writer leaves resource:
  
  ○ both readers enter ⇒ 2:00 reader reads data that is stale; should read 1:30 write
  ○ writer enters and overwrites 12:30 data (never seen) ⇒ 1:00 reader reads data that is too fresh (i.e., missed reading 12:30 data)

• Staleness/freshness can lead to plane or stock-market crash.

• Service readers and writers in temporal order, i.e., first-in first-out (FIFO), but allow multiple concurrent readers.

• Have readers and writers wait on same semaphore ⇒ collapse split binary semaphore.

• But now lose kind of waiting task!

• Introduce shadow queue to retain kind of waiting task on semaphore:
6.4. LOCK PROGRAMMING

uSemaphore entry(1), rwwait(0);  // readers/writers, temporal order
int rwdel = 0, rcnt = 0, wcnt = 0;  // auxiliary counters
enum RW { READER, WRITER };  // kinds of tasks
queue<RW> rw_id;  // queue of kinds

void Reader::main() {
    entry.P();  // pickup baton
    if ( wcnt > 0 || rwdel > 0 ) {  // anybody waiting?
        rw_id.push( READER );  // store kind
        rwdel += 1; entry.V(); rwwait.P(); rwdel -= 1;
        rw_id.pop();
    }
    rcnt += 1;
    if ( rwdel > 0 && rw_id.front() == READER ) {  // more readers ?
        rwwait.V();  // pass baton
    } else
        entry.V();  // put baton down

    // READ
    entry.P();  // exit protocol
    rcnt -= 1;
    if ( rcnt == 0 && rwdel > 0 ) {  // last reader ?
        rwwait.V();  // pass baton
    } else
        entry.V();  // put baton down
}

void Writer::main() {
    entry.P();  // pickup baton
    if ( rcnt > 0 || wcnt > 0 ) {  // store kind
        rw_id.push( WRITER );
        rwdel += 1; entry.V(); rwwait.P(); rwdel -= 1;
        rw_id.pop();
    }
    wcnt += 1;
    entry.V();  // put baton down

    // WRITE
    entry.P();  // pickup baton
    wcnt -= 1;
    if ( rwdel > 0 ) {  // anyone waiting ?
        rwwait.V();  // pass baton
    } else
        entry.V();  // put baton down
}

• Why can task pop front node on shadow queue when unblocked?

6.4.4.5 Solution 5

• Cheat on cooperation:
  ○ allow 2 checks for write instead of 1
  ○ use reader/writer bench and writer chair.

• On exit, if chair empty, unconditionally unblock task at front of reader/writer semaphore.
• ⇒ reader can incorrectly unblock a writer.

• This writer now waits second time but in chair.

• Chair is always checked first on exit (higher priority than bench).

```
uSemaphore entry(1), rwwait(0), wwait(0);
int rwdel = 0, wdel, rcnt = 0, wcnt = 0; // auxiliary counters
void Reader::main() {
  entry.P(); // pickup baton
  if ( wcnt > 0 || wdel > 0 || rwdel > 0 ) {
    rwdel += 1; entry.V(); rwwait.P(); rwdel -= 1;
  }
  rcnt += 1;
  if ( rwdel > 0 ) { // more readers ?
    rwwait.V(); // pass baton
  } else
    entry.V(); // put baton down

  // READ
  entry.P(); // pickup baton
  rcnt -= 1;
  if ( rcnt == 0 ) {
    if ( wdel != 0 ) { // writer waiting ?
      wwait.V(); // pass baton
    } else if ( rwdel > 0 ) { // anyone waiting ?
      rwwait.V(); // pass baton
    } else
      entry.V(); // put baton down
  } else
    entry.V(); // put baton down
}
```
6.4. LOCK PROGRAMMING

```c
void Writer::main() {
    entry.P(); // pickup baton
    if ( rcnt > 0 || wcnt > 0 ) { // first wait ?
        rwdel += 1; entry.V(); rwwait.P(); rwdel -= 1;
        if ( rcnt > 0 ) { // second wait ?
            wdel += 1; entry.V(); wwait.P(); wdel -= 1;
        }
    }
    wcnt += 1;
    entry.V(); // put baton down
    // WRITE
    entry.P(); // pickup baton
    wcnt -= 1;
    if ( rwdel > 0 ) { // anyone waiting ?
        rwwait.V(); // pass baton
    } else
        entry.V(); // put baton down
}
```

6.4.4.6 Solution 6

- Still temporal problem when tasks move from one blocking list to another.
- In solutions, reader/writer entry-protocols have code sequence:
  ```
  ... entry.V(); INTERRUPTED HERE Xwait.P();
  ```
  
- For writer:
  - pick up baton and see readers using resource
  - put baton down, entry.V(), but time-sliced before wait, Xwait.P().
  - another writer does same thing, and this can occur to any depth.
  - writers restart in any order or immediately have another time-slice
  - e.g., 2:00 writer goes ahead of 1:00 writer ⇒ freshness problem.
  
- For reader:
  - pick up baton and see writer using resource
  - put baton down, entry.V(), but time-sliced before wait, Xwait.P().
  - writers that arrived ahead of reader do same thing
  - reader restarts before any writers
  - e.g., 2:00 reader goes ahead of 1:00 writer ⇒ staleness problem.

- Need atomic block and release ⇒ magic like turning off time-slicing.
  ```c
  Xwait.P( entry ); // uC++ semaphore
  ```

- Alternative: ticket
○ readers/writers take ticket (see Section 5.18.9, p. 88) before putting baton down

○ to pass baton, serving counter is incremented and then **WAKE ALL BLOCKED TASKS**

○ each task checks ticket with serving value, and one proceeds while others reblock

○ starvation not an issue as waiting queue is bounded length, but inefficient

- Alternative: private semaphore

  ○ list of **private semaphores**, one for each waiting task, versus multiple waiting tasks on a semaphore.

  ○ add list node before releasing entry lock, which establishes position, then block on private semaphore.

  ○ to pass baton, private semaphore at head of the queue is **V**ed, if present.

  ○ if task blocked on private semaphore, it is unblocked

  ○ if task not blocked due to time-slice, **V** is remembered, and task does not block on **P**.
6.4. LOCK PROGRAMMING

uSemaphore entry(1);
int rcnt = 0, wcnt = 0;

struct RWnode {
    RW rw;       // kinds of task
    uSemaphore sem; // private semaphore
    RWnode( RW rw ) : rw(rw), sem(0) {}
};

queue<RWnode *> rw_id;

void Reader::main() {
    entry.P();        // pickup baton
    if ( wcnt > 0 || ! rw_id.empty() ) { // anybody waiting?
        RWnode r( READER );
        rw_id.push( &r );    // store kind
        rwdel += 1; entry.V(); r.sem.P(); rwdel -= 1;
        rw_id.pop();
    }
    rcnt += 1;
    if ( rwdel > 0 && rw_id.front() == READER ) { // more readers ?
        rw_id.front()->sem.V(); // pass baton
    }
    else
        entry.V();                  // put baton down
    
    // READ
    entry.P();        // pickup baton
    rcnt -= 1;
    if ( rcnt == 0 && rw_id.front() > rw ) { // last reader ?
        rw_id.front()->sem.V(); // pass baton
    }
    else
        entry.V();                  // put baton down
}

void Writer::main() {
    entry.P();        // pickup baton
    if ( rcnt > 0 || wcnt > 0 ) { // resource in use ?
        RWnode w( WRITER );
        rw_id.push( &w );        // remember kind of task
        rwdel += 1; entry.V(); w.sem.P(); rwdel -= 1;
        rw_id.pop();
    }
    wcnt += 1;
    entry.V();
    // WRITE
    entry.P();        // pickup baton
    wcnt -= 1;
    if ( rwdel > 0 ) { // anyone waiting ?
        rw_id.front()->sem.V(); // pass baton
    }
    else
        entry.V();                  // put baton down
}

6.4.4.7 Solution 7

- Ad hoc solution with questionable split-binary semaphores and baton-passing.
• Tasks wait in temporal order on entry semaphore.

• Only one writer ever waits on the writer chair until readers leave resource.

• **Waiting writer blocks holding baton to force other arriving tasks to wait on entry.**

• Semaphore lock is used only for mutual exclusion.

• Sometimes acquire two locks to prevent tasks entering and leaving.

• Release in opposite order.

```c
uSemaphore entry(1); // two locks open
uSemaphore lock(1), wwait(0);
int rcnt = 0, wdel = 0;

void Reader::main() {
    entry.P(); // entry protocol
    lock.P();
    rcnt += 1;
    lock.V();
    entry.V(); // put baton down
    // READ
    lock.P(); // exit protocol
    rcnt -= 1;
    if ( (rcnt == 0 && wdel == 1) ) { // last reader & writer waiting ?
        lock.V();
        wwait.V(); // pass baton
    } else
        lock.V();
} 
```
void Writer::main() {
    entry.P(); // entry protocol
    lock.P();
    if ( rcnt > 0 ) {
        // readers waiting ?
        wdel += 1;
        lock.V();
        wwait.P(); // wait for readers
        wdel -= 1; // unblock with baton
    } else
        lock.V();
    // WRITE
    entry.V(); // exit protocol
}

- Is temporal order preserved?
- While solution is smaller, harder to reason about correctness.
- Does not generalize for other kinds of complex synchronization and mutual exclusion.
7 Concurrent Errors

7.1 Race Condition

- A race condition occurs when there is missing:
  - synchronization
  - mutual exclusion

- Two or more tasks race along assuming synchronization or mutual exclusion has occurred.

- Can be very difficult to locate (thought experiments).
  - Race condition buried in four million lines of C code.
  - “in excess of three million online operational hours in which nothing had ever exercised that bug.”

7.2 No Progress

7.2.1 Live-lock

- Indefinite postponement: “You go first” problem on simultaneous arrival (consuming CPU)

- Caused by poor scheduling in entry protocol:

  ![Diagram of live-lock](image)

- There always exists some mechanism to break tie on simultaneous arrival that deals effectively with live-lock (Oracle with cardboard test).
### 7.2.2 Starvation

- A selection algorithm ignores one or more tasks so they are never executed, i.e., lack of long-term fairness.

- Long-term (infinite) starvation is extremely rare, but short-term starvation can occur and is a problem.

- Like live-lock, starving task might be ready at any time, switching among active, ready and possibly blocked states (consuming CPU).

### 7.2.3 Deadlock

- **Deadlock** is the state when one or more processes are waiting for an event that will not occur.

#### 7.2.3.1 Synchronization Deadlock

- Failure in cooperation, so a blocked task is never unblocked (stuck waiting):

  ```
  int main() {
      uSemaphore s(0);  // closed
      s.P();  // wait for lock to open
  }
  ```

#### 7.2.3.2 Mutual Exclusion Deadlock

- Failure to acquire a resource protected by mutual exclusion.
• Deadlock, unless one of the cars is willing to backup.

• Simple example using semaphores:

```
uSemaphore L1(1), L2(1); // open

// acquire opposite locks
L1.P() L2.P()

// access resource
R1 R2

// acquire opposite locks
L2.P() L1.P()

// access resources
R1 & R2 R2 & R1
```

• There are 5 conditions that must occur for a set of processes to get into Deadlock.

1. A **concrete** shared-resource requiring mutual exclusion, i.e., exists without a task.
   ○ A task “wanting to drive across the intersection” is not a resource.
2. A process holds a resource while waiting for access to a resource held by another process (hold and wait).
3. Once a process has gained access to a resource, the runtime system cannot get it back (no preemption).
4. There exists a circular wait of processes on resources.
5. These conditions must occur simultaneously.

### 7.3 Deadlock Prevention

• Eliminate one or more of the conditions required for a deadlock from an algorithm ⇒ deadlock can never occur.

#### 7.3.1 Synchronization Prevention

• Eliminate all synchronization from a program

• ⇒ no communication

• all tasks must be completely independent, generating results through side-effects.
7.3.2 Mutual Exclusion Prevention

- Deadlock can be prevented by eliminating one of the 5 conditions:

1. no mutual exclusion
   - ⇒ impossible in many cases

2. no hold & wait: do not give any resource, unless all resources can be given
   - ⇒ poor resource utilization
   - possible starvation

3. allow preemption
   - Preemption is dynamic ⇒ cannot apply statically.

4. no circular wait:
   - Control the order of resource allocations to prevent circular wait:
     - Use an ordered resource policy:
     - divide all resources into classes $R_1$, $R_2$, $R_3$, etc.
     - rule: can only request a resource from class $R_i$ if holding no resources from any class $R_j$ for $j \geq i$
     - unless each class contains only one resource, requires requesting several resources simultaneously
     - denote the highest class number for which $T$ holds a resource by $h(T)$
     - if process $T_1$ is requesting a resource of class $k$ and is blocked because that resource is held by process $T_2$, then $h(T_1) < k \leq h(T_2)$
     - as the preceding inequality is strict, a circular wait is impossible
     - in some cases there is a natural division of resources into classes that makes this policy work nicely
     - in other cases, some processes are forced to acquire resources in an unnatural sequence, complicating their code and producing poor resource utilization
5. prevent simultaneous occurrence:
   - Show previous 4 rules cannot occur simultaneously.

### 7.4 Deadlock Avoidance

- Monitor all lock blocking and resource allocation to detect any potential formation of deadlock.

<table>
<thead>
<tr>
<th></th>
<th>deadlock</th>
<th>unsafe</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Achieve better resource utilization, but additional overhead to avoid deadlock.

#### 7.4.1 Banker’s Algorithm

- Demonstrate a safe sequence of resource allocations that ⇒ no deadlock.

- However, requires a process state its maximum resource needs.

<table>
<thead>
<tr>
<th></th>
<th>R1</th>
<th>R2</th>
<th>R3</th>
<th>R4</th>
<th>total resources (TR)</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>4</td>
<td>10</td>
<td>1</td>
<td>1</td>
<td>maximum needed</td>
</tr>
<tr>
<td>T2</td>
<td>2</td>
<td>4</td>

<tr>
<td>T3</td>
<td>4</td>
<td>7</td>
<td>0</td>
<td>1</td>
<td>(N = M - C)</td>
</tr>
</tbody>
</table>

- Is there a safe order of execution that avoids deadlock should each process require its maximum resource allocation?
• If there is a choice of processes to choose for execution, it does not matter which path is taken.

• Example: If T1 or T3 could go to their maximum with the current resources, then choose either. A safe order starting with T1 exists if and only if a safe order starting with T3 exists.

• So a safe order exists (the left column in the table above) and hence the Banker’s Algorithm allows the resource request.

• The check for a safe order is performed for every allocation of resource to a process and then process scheduling is adjusted appropriately.

7.4.2 Allocation Graphs
• One method to check for potential deadlock is to graph processes and resource usage at each moment a resource is allocated.

- Multiple instances are put into a resource so that a specific resource does not have to be requested. Instead, a generic request is made.
• If a graph contains no cycles, no process in the system is deadlocked.
• If any resource has several instances, a cycle $\not\Rightarrow$ deadlock.

\[ T_1 \rightarrow R_1 \rightarrow T_2 \rightarrow R_3 \rightarrow T_3 \rightarrow R_2 \rightarrow T_1 \ (\text{cycle}) \]
\[ T_2 \rightarrow R_3 \rightarrow T_3 \rightarrow R_2 \rightarrow T_2 \ (\text{cycle}) \]
  - If $T_4$ releases its resource, the cycle is broken.

• Create isomorphic graph without multiple instances (expensive and difficult):

\[ R_1 \rightarrow T_1 \rightarrow R_2 \rightarrow T_2 \rightarrow R_3 \rightarrow T_3 \rightarrow R_4 \rightarrow T_4 \]

• If each resource has one instance, a cycle $\Rightarrow$ deadlock.
• Use graph reduction to locate deadlocks:

• Problems:
When there is a choice of tasks, selection is tricky.

For large numbers of processes and resources, detecting cycles is expensive.

There may be large number of graphs to be examined, one for each particular allocation state of the system.

### 7.5 Detection and Recovery

- Instead of avoiding deadlock let it happen and recover.
  - ⇒ ability to discover deadlock
  - ⇒ preemption

- Discovering deadlock is not easy, e.g., build and check for cycles in allocation graph.
  - not on each resource allocation, but every T seconds or every time a resource cannot be immediately allocated

- Recovery involves preemption of one or more processes in a cycle.
  - decision is not easy and must prevent starvation
  - The preemption victim must be restarted, from beginning or some previous checkpoint state, if you cannot guarantee all resources have not changed.
  - even that is not enough as the victim may have made changes before the preemption.

### 7.6 Which Method To Choose?

- Maybe “none of the above”: just ignore the problem
  - if some process is blocked for rather a long time, assume it is deadlocked and abort it
  - do this automatically in transaction-processing systems, manually elsewhere

- Of the techniques studied, only the ordered resource policy turns out to have much practical value.
8 Indirect Communication

- P and V are low level primitives for protecting critical sections and establishing synchronization between tasks.
- Shared variables provide the actual information that is communicated.
- Both of these can be complicated to use and may be incorrectly placed.
- Split-binary semaphores and baton passing are complex.
- Need higher level facilities that perform some of these details automatically.
- Get help from programming-language/compiler.

8.1 Critical Regions

- Declare which variables are to be shared, as in:

```
VAR v : SHARED INTEGER    MutexLock v_lock;
```

- Access to shared variables is restricted to within a REGION statement, and within the region, mutual exclusion is guaranteed.

```
REGION v DO
    v_lock.acquire()
    // critical section
    \dots \// x = v; (read) \ v = y (write)
END REGION
    v_lock.release()
```

- Simultaneous reads are impossible!

- Modify to allow reading of shared variables outside the critical region and modifications in the region.

- Problem: reading partially updated information while a task is updating the shared variable in the region.

- Nesting can result in deadlock.

```
VAR x, y : SHARED INTEGER

task1
REGION x DO
    \dots
    REGION y DO
    \dots
END REGION

task2
REGION y DO
    \dots
    REGION x DO
    \dots
END REGION

dots
```
8.2 Conditional Critical Regions

- Introduce a condition that must be true as well as having mutual exclusion.

\[
\text{REGION } v \text{ DO}
\begin{align*}
& \text{AWAIT } \text{conditional-expression} \\
& \ldots
\end{align*}
\text{END REGION}
\]

- E.g. The consumer from the producer-consumer problem.

\[
\text{VAR } Q : \text{SHARED QUEUE}<\text{INT,10}>
\]

\[
\text{REGION } Q \text{ DO}
\begin{align*}
& \text{AWAIT } \text{NOT EMPTY( } Q \text{ ) } \text{buffer not empty} \\
& \text{take an item from the front of the queue}
\end{align*}
\text{END REGION}
\]

- If the condition is false, the region lock is released and entry is started again (busy waiting).

- If prevent busy waiting, block on queue for shared variable, and on region exit, search for true conditional-expression and unblock.

8.3 Monitor

- A **monitor** is an abstract data type that combines shared data with serialization of its modification.

\[
\_\text{Monitor } \text{name } \{ \\
\text{shared data} \\
\text{members that see and modify the data} \\
\}
\]

- A **mutex member** (short for mutual-exclusion member) is one that does NOT begin execution if there is another active mutex member.

  - ⇒ a call to a mutex member may become blocked waiting entry, and queues of waiting tasks may form.

  - Public member routines of a monitor are implicitly mutex and other kinds of members can be made explicitly mutex (\_\text{Mutex}).

- Basically each monitor has a lock which is Ped on entry to a monitor member and Ved on exit.
8.4 Scheduling (Synchronization)

- A monitor may want to schedule tasks in an order different from the order in which they arrive (bounded buffer, readers/write with staleness/freshness).

- There are two techniques: external and internal scheduling.
  - *external* is scheduling tasks outside the monitor and is accomplished with the accept statement.
  - *internal* is scheduling tasks inside the monitor and is accomplished using condition variables with signal & wait.

```cpp
class Mon {
    MutexLock mlock;
    int v;
public:
    int x(...) { // mutex member
        mlock.acquire();
        ... // int temp = v;
        mlock.release();
        return v; // return temp;
    }
};
```

- Recursive entry is allowed (owner mutex lock), i.e., one mutex member can call another or itself.

- Unhandled exceptions raised within a monitor always release the implicit monitor locks so the monitor can continue to function.

- Destructor is mutex, so ending a block with a monitor or deleting a dynamically allocated monitor, blocks if thread in monitor.

- Atomic counter using a monitor:

```cpp
_Monitor AtomicCounter {
    int counter;
public:
    AtomicCounter( int init = 0 ) : counter( init ) {}
    int inc() { counter += 1; return counter; } // mutex members
    int dec() { counter --= 1; return counter; }
};
```

AtomicCounter a, b, c;
... a.inc(); ... // accessed by multiple threads
... b.dec(); ...
... c.inc(); ...

```cpp
8.4 SCHEDULING (SYNCHRONIZATION)
```

```cpp
• Recursive entry is allowed (owner mutex lock), i.e., one mutex member can call another or itself.

• Unhandled exceptions raised within a monitor always release the implicit monitor locks so the monitor can continue to function.

• Destructor is mutex, so ending a block with a monitor or deleting a dynamically allocated monitor, blocks if thread in monitor.

• Atomic counter using a monitor:

```cpp
_Monitor AtomicCounter {
    int counter;
public:
    AtomicCounter( int init = 0 ) : counter( init ) {}
    int inc() { counter += 1; return counter; } // mutex members
    int dec() { counter --= 1; return counter; }
};
```

AtomicCounter a, b, c;
... a.inc(); ... // accessed by multiple threads
... b.dec(); ...
... c.inc(); ...

8.4 Scheduling (Synchronization)

- A monitor may want to schedule tasks in an order different from the order in which they arrive (bounded buffer, readers/write with staleness/freshness).

- There are two techniques: external and internal scheduling.

  - *external* is scheduling tasks outside the monitor and is accomplished with the accept statement.
  - *internal* is scheduling tasks inside the monitor and is accomplished using condition variables with signal & wait.
8.4.1 External Scheduling

- The accept statement controls which mutex members can accept calls.

- By preventing certain members from accepting calls at different times, it is possible to control scheduling of tasks.

- Each \_Accept defines what cooperation must occur for the accepting task to proceed.

- E.g. Bounded Buffer

```cpp
_Monitor BoundedBuffer {
  int front = 0, back = 0, count = 0;
  int elements[20];

public:
  _Nomutex int query() { return count; }  
  [__Mutex] void insert(int elem);
  [__Mutex] int remove();
};

void BoundedBuffer::insert(int elem) {
  if (count == 20) _Accept(remove);
  elements[back] = elem;
  back = (back + 1) % 20;
  count += 1;
}

int BoundedBuffer::remove() {
  if (count == 0) _Accept(insert);
  int elem = elements[front];
  front = (front + 1) % 20;
  count -= 1;
  return elem;
}
```

- Queues of tasks form outside the monitor, waiting to be accepted into either insert or remove.

- An acceptor blocks until a call to the specified mutex member(s) occurs.

- Accepted call is executed like a conventional member call.

- When the accepted task exits the mutex member (or waits), the acceptor continues.

- If the accepted task does an accept, it blocks, forming a stack of blocked acceptors.

- External scheduling is simple because unblocking (signalling) is implicit.

8.4.2 Internal Scheduling

- Scheduling among tasks inside the monitor.

- A condition is a queue of waiting tasks:

```cpp
uCondition x, y, z[5];
```
• empty returns false if there are tasks blocked on the queue and true otherwise.

• front returns an integer value stored with the waiting task at the front of the condition queue.

• A task waits (blocks) by placing itself on a condition:

  x.wait(); // wait( mutex, condition )

Atomically places the executing task at the back of the condition queue, and allows another task into the monitor by releasing the monitor lock.

• A task on a condition queue is made ready by signalling the condition:

  x.signal();

Removes and makes ready blocked task at front of the condition queue.

• Signaller does not block, so the signalled task must continue waiting until the signaller exits or waits.

• Like a SyncLock, a signal on an empty condition is lost!

• E.g. Bounded Buffer (like binary semaphore solution):

  _Monitor BoundedBuffer {
    _uCondition full, empty;
    int front = 0, back = 0, count = 0;
    int elements[20];
  public:
    _Nomutex int query() { return count; }  
    void insert( int elem ) {
      if ( count == 20 ) empty.wait();
      elements[back] = elem;
      back = ( back + 1 ) % 20;
      count += 1;
      full.signal();
    }
    int remove() {
      if ( count == 0 ) full.wait();
      int elem = elements[front];
      front = ( front + 1 ) % 20;
      count -= 1;
      empty.signal();
      return elem;
    }
  };

• wait() blocks the current thread, and restarts a signalled task or implicitly releases the monitor lock.

• signal() unblocks the thread on the front of the condition queue after the signaller thread blocks or exits.
• `signalBlock()` unblocks the thread on the front of the condition queue and blocks the signaller thread.

• General Model

```java
 Monitor Mon {
   uCondition A, B;
   ...
   public:
     int X(...) {...}
     void Y(...) {...}
};
```

- **entry queue** is FIFO list of calling tasks to the monitor.

• When to use external or internal scheduling?

- External is easier to specify and explain over internal with condition variables.

- However, external scheduling cannot be used if:
  
  - scheduling depends on member parameter value(s), e.g., compatibility code for dating
  - scheduling must block in the monitor but cannot guarantee the next call fulfils cooperation
8.5. READERS/WRITER

- Also, possible to use signal with empty bench (ccode) as chair.

8.5 Readers/Writer

- Solution 3 (Section 6.4.4.3, p. 123), no bargers, 5 rules, not temporal
void startWrite() {
    if ( wcnt !=0 || rcnt != 0 ) writers.wait();
    wcnt = 1;
}
void endWrite() {
    wcnt = 0;
    if ( ! readers.empty() ) readers.signal();
    else writers.signal();
}

• Problem: has the same protocol as P and V.

 ReadersWriter rw;
    readers            writers
    rw.startRead()     rw.startWrite() // 2-step protocol
    rw.endRead()       rw.endWrite()

• Simplify protocol:

 ReadersWriter rw;
    readers            writers
    rw.read(...)       rw.write(...) // 1-step protocol

  ○ Implies only one read/write action, or pass pointer to read/write action.

• Alternative interface:

 _Monitor ReadersWriter {
 _Mutex void startRead() { ... }
 _Mutex void endRead() { ... }
 _Mutex void startWrite() { ... }
 _Mutex void endWrite() { ... }
 public:
 _Nomutex void read(...) {
     startRead();   // acquire mutual exclusion
     endRead();     // release mutual exclusion
 }
 _Nomutex void write(...) {
     startWrite();  // acquire mutual exclusion
     endWrite();    // release mutual exclusion
 }
};

• Alternative interface, and remove wcnt:

8.5. READERS/WRITER

_Monitor ReadersWriter {
    _Mutex void startRead() {
        if ( ! writers.empty() ) readers.wait();
        rcnt += 1;
        readers.signal();
    }
    _Mutex void endRead() { ... }

    public:
    _Nomutex void read(...) {
        startRead(); // acquire mutual exclusion
        // read, no mutual exclusion
        endRead(); // release mutual exclusion
    }
    void write(...) { // acquire mutual exclusion
        if ( rcnt != 0 ) writers.wait(); // release/reacquire
        // write, mutual exclusion
        if ( ! readers.empty() ) readers.signal();
        else writers.signal();
    }
};

• Solution 4 (Section 6.4.4.4, p. 123), shadow queue

_Monitor ReadersWriter {
    int rcnt = 0, wcnt = 0;
    uCondition RWers;
    enum RW { READER, WRITER };
    public:
    void startRead() {
        if ( wcnt != 0 | | ! RWers.empty() ) RWers.wait( READER );
        rcnt += 1;
        if ( ! RWers.empty() & & RWers.front() == READER ) RWers.signal();
    }
    void endRead() {
        rcnt -= 1;
        if ( rcnt == 0 ) RWers.signal();
    }

    void startWrite() {
        if ( wcnt != 0 | | rcnt != 0 ) RWers.wait( WRITER );
        wcnt = 1;
    }
    void endWrite() {
        wcnt = 0;
        RWers.signal();
    }
};
- Solution 8, external scheduling

```cpp
_Monitor ReadersWriter {
    int rcnt = 0, wcnt = 0;
    public:
    void endRead() {
        rcnt -= 1;
    }
    void endWrite() {
        wcnt = 0;
    }
    void startRead() {
        if ( wcnt > 0 ) _Accept( endWrite );
        rcnt += 1;
    }
    void startWrite() {
        if ( wcnt > 0 ) _Accept( endWrite );
        else while ( rcnt > 0 ) _Accept( endRead );
        wcnt = 1;
    }
};
```

- Why has the order of the member routines changed?
- An exception raised in a monitor member propagates to the caller’s thread.
- A RendezvousFailure exception is also raised at monitor acceptor’s thread to identify failed cooperation.

```cpp
_Monitor M {
    public:
    void mem1() {
        try {
            ... if ( ... ) _Accept( mem2 ); ...
        } catch( uMutexFailure::RendezvousFailure ) { // implicitly enabled
            // deal with rendezvous failure
        } // try
    }
    void mem2() {
        ... if ( ... ) _Throw E(); ... // E goes to caller
    } // uRendezvousFailure goes to “this”
};
```

- RendezvousFailure implicitly enabled ⇒ _Enable block unnecessary.
- For multiple _Accept clauses
8.6 CONDITION, SIGNAL, WAIT VS. COUNTING SEMAPHORE, V, P

flag variable required to know which member failed.

- **Nested monitor problem**: acquire monitor (lock) $M_1$, call to monitor $M_2$, and wait on condition in $M_2$.

  ![Diagram](image)

  $M_1$ acquire block release $M_2$

  - Monitor $M_2$’s mutex lock is released by wait, but monitor $M_1$’s monitor lock is NOT released $\Rightarrow$ potential deadlock.

  - Same problem occurs with locks.

  - Releasing all locks can inadvertently release a lock, e.g., incorrectly release $M_0$ before $M_1$.

8.6 Condition, Signal, Wait vs. Counting Semaphore, V, P

- There are several important differences between these mechanisms:
  
  - wait always blocks, P only blocks if semaphore = 0
  
  - if signal occurs before a wait, it is lost, while a V before a P affects the P

  - multiple Vs may start multiple tasks simultaneously, while multiple signals only start one task at a time because each task must exit serially through the monitor

- Possible to simulate P and V using a monitor:

  ```cpp
  _Monitor semaphore {
  int sem;
  uCondition semcond;
  public:
  semaphore( int cnt = 1 ) : sem( cnt ) {} 
  void P() {
      if ( sem == 0 ) semcond.wait();
      sem -= 1;
  }
  void V() {
      sem += 1;
      semcond.signal();
  }
  }
  ```

- Can this simulation be reduced?
8.7 Monitor Types

- **explicit scheduling** occurs when:
  - An accept statement blocks the active task on the acceptor stack and makes a task ready from the specified mutex member queue.
  - A signal moves a task from the specified condition to the signalled stack.

- **implicit scheduling** occurs when a task waits in or exits from a mutex member, and a new task is selected first from the A/S stack, then the entry queue.

<table>
<thead>
<tr>
<th>explicit scheduling</th>
<th>internal scheduling (signal)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>external scheduling (accept)</td>
</tr>
<tr>
<td>implicit scheduling</td>
<td>monitor selects (wait/exit)</td>
</tr>
</tbody>
</table>

- Monitors are classified by the implicit scheduling (who gets control) of the monitor when a task waits or signals or exits.

- Implicit scheduling can select from the calling (C), signalled (W) and signaller (S) queues.

  - Assigning different priorities to these queues creates different monitors (e.g., $C < W < S$).
  - Many of the possible orderings can be rejected as they do not produce a useful monitor (e.g., $W < S < C$).
### Implicit Signal

- Monitors either have an explicit signal (statement) or an implicit signal (automatic signal).
- The implicit signal monitor has no condition variables or explicit signal statement.
- Instead, there is a `waitUntil` statement, e.g.:

```
waitUntil logical-expression
```

- The implicit signal causes a task to wait until the conditional expression is true.

```c
Monitor BoundedBuffer {
    int front = 0, back = 0, count = 0;
    int elements[20];

    Nomutex int query() { return count; }
    void insert( int elem ) {
        waitUntil count != 20; // not in uC++
        elements[back] = elem;
        back = ( back + 1 ) % 20;
        count += 1;
    }

    int remove() {
        waitUntil count != 0; // not in uC++
        int elem = elements[front];
        front = ( front + 1 ) % 20;
        count -= 1;
        return elem;
    }
};
```
• Additional restricted monitor-type requiring the signaller exit immediately from monitor (i.e., signal \( \Rightarrow \) return), called **immediate-return signal**.
  
  ◦ not powerful enough to handle all cases, e.g., dating service, but optimizes the most common case of signal before return.

• Remaining monitor types:

<table>
<thead>
<tr>
<th>signal type</th>
<th>priority</th>
<th>no priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blocking</td>
<td>Priority Blocking (Hoare)</td>
<td>No Priority Blocking</td>
</tr>
<tr>
<td></td>
<td>( C &lt; S &lt; W ) (( \mu )C++ signalBlock)</td>
<td>( C = S &lt; W )</td>
</tr>
<tr>
<td>Nonblocking</td>
<td>Priority Nonblocking</td>
<td>No Priority Nonblocking</td>
</tr>
<tr>
<td></td>
<td>( C &lt; W &lt; S ) (( \mu )C++ signal)</td>
<td>( C = W &lt; S ) (Java/C#)</td>
</tr>
<tr>
<td>Implicit Signal</td>
<td>Priority</td>
<td>No Priority</td>
</tr>
<tr>
<td></td>
<td>Implicit Signal</td>
<td>Implicit Signal</td>
</tr>
<tr>
<td></td>
<td>( C &lt; W )</td>
<td>( C = W )</td>
</tr>
</tbody>
</table>

◦ no-priority blocking requires the **signaller task** to recheck the waiting condition in case of a barging task.
  \( \Rightarrow \) use a **while** loop around a signal

◦ no-priority non-blocking requires the **signalled task** to recheck the waiting condition in case of a barging task.
  \( \Rightarrow \) use a **while** loop around a **wait**

◦ implicit (automatic) signal is good for **prototyping** but have poor performance.

◦ priority-nonblocking has no barging and optimizes signal before return (supply cooperation).

◦ priority-blocking has no barging and handles internal cooperation within the monitor (wait for cooperation).

• coroutine monitor (**_Cormonitor**)

  ◦ coroutine with implicit mutual exclusion on calls to specified member routines:

    ```
    _Mutex _Coroutine C { // _Cormonitor
      void main() {
        ... suspend() ...
        ... suspend() ...
      }
    }
    
    public:
      void m1( ... ) { ... resume(); ... } // mutual exclusion
      void m2( ... ) { ... resume(); ... } // mutual exclusion
      ... // destructor is **ALWAYS** mutex
    }
    ```

  ◦ can use resume(), suspend(), condition variables (wait(), signal(), signalBlock()) or **Accept** on mutex members.

  ◦ coroutine can now be used by multiple threads, e.g., coroutine print-formatter accessed by multiple threads.
8.8 Java Monitor

- Java has **synchronized** class members (i.e., _Mutex members but incorrectly named), and a **synchronized** statement.

- All classes have one implicit condition variable and these routines to manipulate it:

  ```java
  public wait();
  public notify();
  public notifyAll()
  ```

- Java concurrency library has multiple conditions but incompatible with language condition (see Section 11.5.1, p. 210).

- Internal scheduling is no-priority nonblocking ⇒ barging
  
  - wait statements must be in while loops to recheck conditions.

- Bounded buffer:

  ```java
  class Buffer {
    // buffer declarations
    private int count = 0;
    public synchronized void insert( int elem ) {
      while ( count == Size ) wait();  // busy-waiting
      // add to buffer
      count += 1;
      if ( count == 1 ) notifyAll();
    }
    public synchronized int remove() {
      while ( count == 0 ) wait();  // busy-waiting
      // remove from buffer
      count -= 1;
      if ( count == Size - 1 ) notifyAll();
      return elem;
    }
  }
  ```

- Only one condition queue, producers/consumers wait together ⇒ unblock all tasks.

- Only one condition queue ⇒ certain solutions are difficult or impossible.

- Erroneous Java implementation of barrier:
class Barrier {  // monitor
    private int N, count = 0;
    public Barrier( int N ) { this.N = N; }
    public synchronized void block() {
        count += 1;  // count each arriving task
        if ( count < N )
            try { wait(); } catch( InterruptedException e ) {}
        else  // barrier full
            notifyAll();  // wake all barrier tasks
        count -= 1;  // uncount each leaving task
    }
}

- Nth task does notifyAll, leaves monitor and performs its ith step, and then races back ( barging) into the barrier before any notified task restarts.
- It sees count still at N and incorrectly starts its ith+1 step before the current tasks have completed their ith step.

• Fix by modifying code for Nth task to set count to 0 ( barging avoidance).

    else {  // barrier full
        count = 0;  // reset count
        notifyAll();  // wake all barrier tasks
    }

• Technically, still wrong because of spurious wakeup ⇒ require loop around wait.

    if ( count < N )
        while ( ??? ) // cannot be count < N as count is always < N
            try { wait(); } catch( InterruptedException e ) {}

• Requires more complex implementation.

    class Barrier {  // monitor
        private int N, count = 0, generation = 0;
        public Barrier( int N ) { this.N = N; }
        public synchronized void block() {
            int mygen = generation;
            count += 1;  // count each arriving task
            if ( count < N )  // barrier not full ? => wait
                while ( mygen == generation )
                    try { wait(); } catch( InterruptedException e ) {}
            else  // barrier full
                count = 0;  // reset count
                generation += 1;  // next group
                notifyAll();  // wake all barrier tasks
        }
    }

• Misconception of building condition variables in Java with nested monitors:
class Condition {
   // try to build condition variable
   public synchronized void Wait() {
      try { wait(); } catch (InterruptedException ex ) {};
   }
   public synchronized void Notify() { notify(); }
}

class BoundedBuffer {
   // buffer declarations
   private Condition full = new Condition(), empty = new Condition();
   public synchronized void insert( int elem ) {
      while ( count == NoOfElems ) empty.Wait(); // block producer
      // add to buffer
      count += 1;
      full.Notify(); // unblock consumer
   }
   public synchronized int remove() {
      while ( count == 0 ) full.Wait(); // block consumer
      // remove from buffer
      count -= 1;
      empty.Notify(); // unblock producer
      return elem;
   }
}

• Deadlocks at empty.Wait()/full.Wait() as buffer monitor-lock is not released.
9 Direct Communication

- Monitors work well for passive objects that require mutual exclusion because of sharing.
- However, communication among tasks with a monitor is indirect.
- Problem: point-to-point with reply indirect communication:

```
Task₁  monitor  Task₂
  |  copy data  |
  |      ↘      |
  |      ↘      |
  |    copy data|
  |      ↘      |
  |     copy result|
  |      ↘      |
  |    copy result|
```

- Point-to-point with reply direct communication:

```
Task₁  Task₂
  |  copy data  |
  |      ↘      |
  |      ↘      |
  |    rendezvous|
  |      ↘      |
  |     process data|
  |      ↘      |
  |    copy result|
  |      ↘      |
  |    copy result|
```

- Tasks can communicate directly by calling each others member routines.

9.1 Task

- A task is like a coroutine, because it has a distinguished member, (task main), which has its own execution state.
- A task is unique because it has a thread of control, which begins execution in the task main when the task is created.
- A task is like a monitor because it provides mutual exclusion (and synchronization) so only one thread is active in the object.
  - public members of a task are implicitly mutex and other kinds of members can be made explicitly mutex.
○ external scheduling allow direct calls to mutex members (task’s thread blocks while caller’s executes)

○ without external scheduling, tasks must *call out* to communicate ⇒ third party, or somehow emulate external scheduling with internal.

- In general, basic execution properties produce different abstractions:

<table>
<thead>
<tr>
<th>object properties</th>
<th>member routine properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread</td>
<td>stack</td>
</tr>
<tr>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

- When thread or stack is missing it comes from calling object.

- Abstractions are not ad-hoc, rather derived from basic properties.

- Each of these abstractions has a particular set of problems it can solve, and therefore, each has a place in a programming language.

### 9.2 Scheduling

- A task may want to schedule access to itself by other tasks in an order different from the order in which requests arrive.

- As for monitors, there are two techniques: external and internal scheduling.

#### 9.2.1 External Scheduling

- As for a monitor (see Section 8.4.1, p. 144), the accept statement can be used to control which mutex members of a task can accept calls.
9.2. SCHEDULING

```cpp
_Task BoundedBuffer {
    int front, back, count;
    int Elements[20];

    public:
        BoundedBuffer() : front(0), back(0), count(0) {}

        public int query() { return count; }

        void insert(int elem) {
            Elements[back] = elem;
            back = (back + 1) % 20;
            count += 1;
        }

        int remove() {
            int elem = Elements[front];
            front = (front + 1) % 20;
            count -= 1;
            return elem;
        }

    protected:
        void main() {
            for (;;) {
                // INFINITE LOOP!!!
                // _Accept( insert, remove );
                _When (count != 20) _Accept( insert ) { // after call
                    or _When (count != 0) _Accept( remove ) { // after call
                        } // _Accept
            }
        }
    }
};
```

• _Accept( m1, m2 ) S1 ≡ _Accept( m1 ) S1; or _Accept( m2 ) S1;
  if ( C1 || C2 ) S1 ≡ if ( C1 ) S1; else if ( C2 ) S1; // S2

• Extended version allows different _When/code after call for each accept.

• The _When clause is like the condition of conditional critical region:
  ◦ The condition must be true (or omitted) and a call to the specified member must exist before a member is accepted.

• If all the accepts are conditional and false, the statement does nothing (like switch with no matching case).

• If some conditionals are true, but there are no outstanding calls, the acceptor is blocked until a call to an appropriate member is made.

• If several members are accepted and outstanding calls exist to them, a call is selected based on the order of the _Accepts.
  ◦ Hence, the order of the _Accepts indicates their relative priority for selection if there are several outstanding calls.
• Is there a potential starvation problem?

• Why are accept statements moved from member routines to the task main?

• Why is BoundedBuffer::main defined at the end of the task?

• Equivalence using if statements:

  ```
  if ( 0 < count && count < 20 ) _Accept( insert, remove ); // not full/empty
  else if ( count < 20 ) _Accept( insert ); // not full
  else /* if ( 0 < count ) */ _Accept( remove ); // not empty
  ```

• Generalize from 2 to 3 conditionals/members:

  ```
  if ( C1 && C2 && C3 ) _Accept( M1, M2, M3 );
  else if ( C1 && C2 ) _Accept( M1, M2 );
  else if ( C1 && C3 ) _Accept( M1, M3 );
  else if ( C2 && C3 ) _Accept( M2, M3 );
  else if ( C1 ) _Accept( M1 );
  else if ( C2 ) _Accept( M2 );
  else if ( C3 ) _Accept( M3 );
  ```

• Necessary to ensure that for every true conditional, only the corresponding members are accepted.

• $2^N - 1$ if statements needed to simulate $N$ accept clauses.

• The acceptor is pushed on the top of the A/S stack and normal implicit scheduling occurs (C < W < S).
• Once accepted call completes or caller wait(s), the statement after the accepting _Accept clause is executed and the accept statement is complete.

• If there is a terminating _Else clause and no _Accept can be executed immediately, the terminating _Else clause is executed.

    _Accept( ... ) {
    } or _Accept( ... ) {
    } _Else { ... } // executed if no callers

  ◦ Hence, the terminating _Else clause allows a conditional attempt to accept a call without the acceptor blocking.

• To achieve greater concurrency in the bounded buffer, change to:

    void insert( int elem ) {
        Elements[back] = elem;
    }
    int remove() {
        return Elements[front];
    }

protected:
    void main() {
        for ( ;; ) {
            _When ( count != 20 ) _Accept( insert ) {
                back = (back + 1) % 20;
                count += 1;
            } or _When ( count != 0 ) _Accept( remove ) {
                front = (front + 1) % 20;
                count -= 1;
            } // _Accept
        }
    }

9.2.2 Internal Scheduling

• Scheduling among tasks inside the monitor.

• As for monitors, condition, signal and wait are used.
 CHAPTER 9. DIRECT COMMUNICATION

```java
_Task BoundedBuffer {
   _uCondition full, empty;
   int front, back, count;
   int Elements[20];
   public:
   BoundedBuffer() : front(0), back(0), count(0) {}  
   _Nomutex int query() { return count; }
   void insert( int elem ) {  
      if ( count == 20 ) empty.wait();
      Elements[back] = elem;
      back = ( back + 1 ) % 20;
      count += 1;
      full.signal();
   }

   int remove() {  
      if ( count == 0 ) full.wait();
      int elem = Elements[front];
      front = ( front + 1 ) % 20;
      count -= 1;
      empty.signal();
      return elem;
   }
   protected:
   void main() {  
      for ( ;; ) {  
         _Accept( insert, remove );
         // do other work  
      }
   }
};
```

- Requires combination of internal and external scheduling.

- Rendezvous is logically pending when wait restarts _Accept task, but post _Accept statement still executed (no RendezvousFailure).
  - Acceptor must eventually complete rendezvous for waiting caller.

- Try moving code to achieve greater concurrency.
9.2. SCHEDULING

```c
void insert( int elem ) {
    if ( count == 20 ) empty.wait(); // only wait if necessary
    Elements[back] = elem;
}

int remove() {
    if ( count == 0 ) full.wait(); // only wait if necessary
    return Elements[front];
}

protected:
    void postInsert() { // helper members
        back = ( back + 1 ) % size;
        count += 1;
    }

    void postRemove() {
        front = ( front + 1 ) % size;
        count -= 1;
    }

}

void main() {
    for ( ;; ) {
        if ( count != 20 ) { // producer did not wait?
            postInsert();
            if ( ! full.empty() ) { // waiting consumers?
                full.signal(); // wake and adjust
                postRemove();
            }
        }
        else {
            if ( count != 0 ) { // consumer did not wait?
                postRemove();
                if ( ! empty.empty() ) { // waiting producers?
                    empty.signal(); // wake and adjust
                    postInsert();
                }
            }
        }
    }
}
```

- Must prevent starvation by producers (use _When_ or flip _Accept_ clauses).

- Must change signal to signalBlock.
Signalled tasks cannot leave because buffer task continues in monitor.
Signal-blocked tasks leave immediately because buffer-task blocks.

9.2.3 Accepting the Destructor

- Common way to terminate a task is to have a stop member:

```
(Task BoundedBuffer {
  public:
  ... 
  void stop() {} // empty 
  private:
  void main() {
    // start up 
    for ( ; ; ) {
      _Accept( stop ) { // terminate ?
        break;
      } or _When ( count != 20 ) _Accept( insert ) {
        ...
      } or _When ( count != 0 ) _Accept( remove ) {
        ...
      } // _Accept
    } // _Accept
    // close down
  }
}
```

- Call stop when task is to stop:

```
int main() {
  BoundedBuffer buf;
  // create producer & consumer tasks 
  // delete producer & consumer tasks 
  buf.stop(); // no outstanding calls to buffer 
  // maybe do something else with buf (print statistics) 
} // delete buf
```
9.3. INCREASING CONCURRENCY

• If termination and deallocation follow one another, accept destructor:

```c
void main() {
    for ( ;; ) {
        _Accept( ~BoundedBuffer ) {
            break;
        } or _When ( count != 20 ) _Accept( insert ) { . . .
        } or _When ( count != 0 ) _Accept( remove ) { . . .
        } // _Accept
    } // close down
}
```

• However, the semantics for accepting a destructor are different from accepting a normal mutex member.

• When the call to the destructor occurs, the caller blocks immediately if there is thread active in the task because a task’s storage cannot be deallocated while in use.

• When the destructor is accepted, the caller is blocked and pushed onto the A/S stack instead of the acceptor.

• Therefore, control restarts at the accept statement without executing the destructor member.

• Allows mutex object to clean up before termination (monitor or task).

• Task now behaves like a monitor because its thread is halted.

• Only when the caller to the destructor is popped off the A/S stack by the implicit scheduling is the destructor executed.

• The destructor can reactivate any blocked tasks on condition variables and/or the acceptor/signalled stack.

9.3 Increasing Concurrency

• 2 task involved in direct communication: client (caller) & server (callee)

• possible to increase concurrency on both the client and server side

9.3.1 Server Side

• Server manages a resource and server thread should introduce additional concurrency (assuming no return value).
No Concurrency

_Task server1 {
    public:
    void mem1(...) { S1 }
    void mem2(...) { S2 }
    void main() {
        ... 
        _Accept( mem1 );
        or _Accept( mem2 );
    }
}

Some Concurrency

_Task server2 {
    public:
    void mem1(...) { S1.copy-in }
    int  mem2(...) { S2.copy-out }
    void main() {
        ... 
        _Accept( mem1 ) { S1.work }
        or _Accept( mem2 ) { S2.work };
    }
}

- No concurrency in left example as server is blocked, while client does work.
- Alternatively, client blocks in member, server does work, and server unblocks client.
- Some concurrency possible in right example if service can be factored into administrative (S1.copy) and work (S1.work) code.
  - i.e., move code from the member to statement executed after member is accepted.
- Small overlap between client and server (client gets away earlier) increasing concurrency.

9.3.1.1 Internal Buffer

- The previous technique provides buffering of size 1 between the client and server.
- Use a larger internal buffer to allow clients to get in and out of the server faster?
- I.e., an internal buffer can be used to store the arguments of multiple clients until the server processes them.
- However, there are several issues:
  - Unless the average time for production and consumption is approximately equal with only a small variance, the buffer is either always full or empty.
  - Because of the mutex property of a task, no calls can occur while the server is working, so clients cannot drop off their arguments.
    The server could periodically accept calls while processing requests from the buffer (awkward).
  - Clients may need to wait for replies, in which case a buffer does not help unless there is an advantage to processing requests in non-FIFO order.
- Only way to free server’s thread to receive new requests and return finished results to clients is add another thread.
- Additional thread is a worker task that calls server to get work from buffer and return results to buffer.
- Note, customer (client), manager (server) and employee (worker) relationship.
9.3. INCREASING CONCURRENCY

- Number of workers has to balance with number of clients to maximize concurrency (bounded-buffer problem).

9.3.1.2 Administrator

- An administrator is a server managing multiple clients and worker tasks.

- The key is that an administrator does little or no “real” work; its job is to manage.

- Management means delegating work to others, receiving and checking completed work, and passing completed work on.

- An administrator is called by others, so an administrator is always accepting calls.

- An administrator makes no call to another task because calling may block the administrator.

- An administrator usually maintains a list of work to pass to worker tasks.

- Typical workers are:

  **timer** - prompt the administrator at specified time intervals
  
  **notifier** - perform a potentially blocking wait for an external event (key press)
  
  **simple worker** - do work given to them by and return the result to the administrator
  
  **complex worker** - do work given to them by administrator and interact directly with client of the work
  
  **courier** - perform a potentially blocking call on behalf of the administrator
9.3.2 Client Side

• While a server can attempt to make a client’s delay as short as possible, not all servers do it.

• In some cases, a client may not have to wait for the server to process a request (producer/consumer problem)

• This can be accomplished by an asynchronous call from the client to the server, where the caller does not wait for the call to complete.

• Asynchronous call requires implicit buffering between client and server to store the client’s arguments from the call.

• \(\mu C++\) provides only synchronous call, i.e., the caller is delayed from the time the arguments are delivered to the time the result is returned (like a procedure call).

• It is possible to build asynchronous facilities out of the synchronous ones and vice versa.

9.3.2.1 Returning Values

• If a client only drops off data to be processed by the server, the asynchronous call is simple.

• However, if a result is returned from the call, i.e., from the server to the client, the asynchronous call is significantly more complex.

• To achieve asynchrony in this case, a call must be divided into two calls:

  ```
  callee.start(arg);  // provide arguments
  // caller performs other work asynchronously
  result = callee.wait();  // obtain result
  ```

• Not same as START/WAIT because server thread exists.
9.3. INCREASING CONCURRENCY

- many-to-one versus one-to-one

- Time between calls allows calling task to execute asynchronously with task performing operation on the caller’s behalf.

- If result is not ready when second call is made
  - caller blocks
  - caller has to call again (poll).

- However, this requires a protocol so that when the client makes the second call, the correct result can be found and returned.

9.3.2.2 Tickets

- One form of protocol is the use of a token or ticket.

- The first part of the protocol transmits the arguments specifying the desired work and a ticket (like a laundry ticket) is returned immediately.

- The second call pulls the result by passes the ticket.

- The ticket is matched with a result, and the result is returned if available or the caller is blocks or polls until the result is available.

- However, protocols are error prone because the caller may not obey the protocol (e.g., never retrieve a result, use the same ticket twice, forged ticket).

9.3.2.3 Call-Back Routine

- Another protocol is to transmit (register) a routine on the initial call.

- When the result is ready, the routine is called by the task generating the result, passing it the result.

- The call-back routine cannot block the server; it can only store the result and set an indicator (e.g., V a semaphore) known to the client.

- The original client must poll the indicator or block until the indicator is set.

- The advantage is that the server can push the result back to the client faster (nagging the client to pickup).

- Also, the client can write the call-back routine, so they can decide to poll or block or do both.
9.3.2.4 Futures

- A future provides the same asynchrony as above but without an explicit protocol.
- The protocol becomes implicit between the future and the task generating the result.
- Further, it removes the difficult problem of when the caller should try to retrieve the result.
- In detail, a future is an object that is a subtype of the result type expected by the caller.
- Instead of two calls as before, a single call is made, passing the appropriate arguments, and a future is returned.

\[
\text{future} = \text{callee.work( arg );} \quad // \text{provide arguments, return future}
\]
\[
\text{// perform other work asynchronously}
\]
\[
i = \text{future} + \ldots; \quad \quad // \text{obtain result, may block if not ready}
\]

- The future is returned immediately and it is empty.
- The caller “believes” the call completed and continues execution with an empty result value.
- The future is filled in at some time in the “future”, when the result is calculated.
- If the caller tries to use the future before its value is filled in, the caller is implicitly blocked.
- The general design for a future is:

```cpp
class Future : public ResultType {
    friend _Task server; \quad // allow server to access internal state
    ResultType result;
    uSemaphore avail;
    Future* link; \quad \quad // intrusive data structure
public:
    Future() : avail(0) {}  
    ResultType get() {  
        avail.P(); \quad // wait for result
        return result;
    }
};
```

- the semaphore is used to block the caller if the future is empty
- the link field is used to chain the future onto a server work-list.

- Unfortunately, the syntax for retrieving the value of the future is awkward as it requires a call to the get routine.
- Also, in languages without garbage collection, the future must be explicitly deleted.
- \( \mu \text{C++} \) provides two forms of template futures, which differ in storage management.
  - Explicit-Storage-Management future (Future_ESM<T>) must be allocated and deallocated explicitly by the client.
9.3. INCREASING CONCURRENCY

- Implicit-Storage-Management future (Future_ISM<T>) automatically allocates and frees storage (when future no longer in use, GC).

- Focus on Future_ISM as simpler to use but less efficient in certain cases.

- Basic set of operations for both types of futures, divided into client and server operations.

Client

- Future value:

```cpp
#include <uFuture.h>
Server server;  // server thread handles async calls
Future_ISM<int> f[10];
for ( int i = 0; i < 10; i += 1 ) {
    f[i] = server.perform( i );  // asynchronous server call
}
// work asynchronously while server processes requests
for ( int i = 0; i < 10; i += 1 ) {
    // retrieve async results
    osacquire acq( cout );  // combine output
    int v = f[i]();  // synchronize, read, and copy
    cout << f[i]() << ' ' ;  // synchronize and read
    cout << f[i] + i << endl;  // cheap read after synchronize
}
f[3] = 3; // DISALLOWED: OTHER THREADS READING VALUE
...f[3].reset(); // reset future => empty and can be reused (be careful)
...f[3].cancel(); // attempt to stop server and clients from usage
```

- Why not combine: osacquire( cout ) << f[i]() << ' ' << f[i] + 1 << end:?  

- Future pointer:

```cpp
#include <uFuture.h>
Server server;  // server thread handles async calls
int val
Future_ISM<int *> fval;
fval = server.perform( val );  // async call to server (change val by reference)
// work asynchronously while server processes requests
osacquire( cout ) << *fval() << endl;  // synchronize on retrieve value
val = 3;  // ALLOWED: BUT FUTURE POINTER IS STILL READ-ONLY
```

available – returns true if asynchronous call completed, otherwise false. complete ⇒ result available, server raised exception, or call cancelled

operator() – (function call) returns read-only copy of future result.

block if future unavailable; raise exception if exception returned by server.

future result can be retrieved multiple times by any task (⇒ read-only) until the future is reset or destroyed.
**operator** \( T \) – (conversion to type \( T \)) returns read-only copy of future result.

*Only allowed after blocking access or call to available returns true.*

Low-cost way to get future result *after* the result is delivered; raise exception if exception returned by server.

reset – mark future as empty \( \Rightarrow \) current future value is unavailable \( \Rightarrow \) future can be reused.

cancel – attempts to cancel the asynchronous call the future refers to.

Clients waiting for the result are unblocked, and exception of type uCancellation is raised at them.

cancelled – returns true if the future is cancelled and false otherwise.

**Server**

```cpp
struct Work {
    int i; // argument(s)
    Future(ISM<int>) result; // result
    Work( int i ) : i( i ) {} // called by clients
    Future(ISM<int>) perform( int i ) { // called by clients
        Work *w = new Work( i ); // create work request
        requests.push_back( w ); // add to list of requests
        return w->result; // return future in request
    }
    // server or server's worker does
    Work *w = requests.front(); // take next work request
    requests.pop_front(); // remove request
    int r = ...; // compute result using argument w->i
    w->result.delivery( r ); // insert result into future
    delete w; // CLIENT FUTURE NOT DELETED (REF COUNTING)
};
```

delivery( T result ) – copy result to be returned to the client(s) into the future, unblocking clients waiting for the result.

exception( uBaseEvent * cause ) – copy a server-generated exception into the future, and the exception cause is thrown at waiting clients.

```cpp
<Event E {};
Future(ISM<int>) result;
result.exception( new E ); // deleted by future
```

exception deleted by reset or when future deleted
Complex Future Access

- **select statement** waits for one or more **heterogeneous** futures based on logical selection-criteria.

- Simplest select statement has a single **_Select** clause, e.g.:
  \[
  _\text{Select}( \text{selector-expression} );
  \]

- Selector-expression must be satisfied before execution continues.

- For a single future, the expression is satisfied if and only if the future is available.
  \[
  _\text{Select}( \ f1 \ );
  \]

- Selector is select blocked until f1.available() is true.

- Not equivalent to calling future access-operator (f1()), which returns the future value or throws an exception.

- Multiple futures may appear in a compound selector-expression, related using logical operators || and &&:
  \[
  _\text{Select}( \ f1 \ || \ f2 \ && \ f3 \ );
  \]

- Normal operator precedence applies: **_Select**( f1 || ( f2 && f3 ) ).

- Execution waits until either future f1 is available or both futures f2 and f3 are available.

- For any selector expression containing an || operator, some futures in the expression may be unavailable after the selector expression is satisfied.

- E.g., in the above, if future f1 becomes available, neither, one or both of f2 and f3 may be available.

- **or** and **and** keywords relate the **_Select** clauses like operators || and && relate futures in a select-expression, including precedence.
  \[
  _\text{Select}( \ f1 \ || \ f2 \ && \ f3 \ ); \equiv \ _\text{Select}( \ f1 \ )
  \quad \text{or} \quad _\text{Select}( \ f2 \ )
  \quad \text{and} \quad _\text{Select}( \ f3 \ );
  \]

- Parentheses may be used to specify evaluation order.
  \[
  _\text{Select}( \ ( \ f1 \ || \ ( \ f2 \ && \ f3 \ ) ) \ ) \equiv \ ( \ _\text{Select}( \ f1 \ )
  \quad \text{or} \quad ( \ _\text{Select}( \ f2 \ )
  \quad \text{and} \quad _\text{Select}( \ f3 \ ) ) \ ) ;
  \]

- A **_Select** clause may be guarded with a logical expression and have code executed after a future receives a value:
• Each _Select-clause action is executed when its sub-selector expression is satisfied, i.e., when each future becomes available.

• However, control does not continue until the selector expression associated with the entire statement is satisfied.

• E.g., if f2 becomes available, statement-2 is executed but the selector expression for the entire statement is not satisfied so control blocks again.

• When either f1 or f3 become available, statement-1 or 3 is executed, and the selector expression for the entire statement is satisfied so control continues.

• Within the action statement, it is possible to access the future using the non-blocking access-operator since the future is known to be available.

• An action statement is triggered only once for its selector expression, even if the selector expression is compound.

• In statement-2, both futures f2 and f3 are available (non-blocking access for both).

• However, for |:

• In statement-1, only one future f1 or f2 caused the action to be triggered.

• Hence, it is necessary to check which of the two futures is available.

• A select statement can be non-blocking using a terminating _Else clause, e.g.:
• The _Else clause must be the last clause of a select statement.

• If its guard is true or omitted and the select statement is not immediately true, then the action for the _Else clause is executed and control continues.

• If the guard is false, the select statement blocks as if the _Else clause is not present.
10 Optimization

- A computer with infinite memory and speed requires no optimizations to use less memory or run faster (space/time).

- With finite resources, optimization is useful/necessary to conserve resources and for good performance.

- Furthermore, most programs are not written in optimal order or in minimal form.
  - OO, Functional, SE are seldom optimal approaches on von Neumann machine.

- General forms of optimizations are:
  - reordering: data and code are reordered to increase performance in certain contexts.
  - eliding: removal of unnecessary data, data accesses, and computation.
  - replication: processors, memory, data, code are duplicated because of limitations in processing and communication speed (speed of light).

- Optimized program must be isomorphic to original ⇒ produce same result for fixed input.

- Kinds of optimizations are restricted by the kind of execution environment.

10.1 Sequential Optimizations

- Most programs are sequential; even concurrent programs are
  - (large) sections of sequential code per thread connected by
  - small sections of concurrent code where threads interact (protected by synchronization and mutual exclusion (SME))

- Sequential execution presents simple semantics for optimization.
  - operations occur in program order, i.e., sequentially

- Dependencies result in partial ordering among a set of statements (precedence graph):
  - data dependency (R ⇒ read, W ⇒ write)
    
    \[
    \begin{align*}
    R_x & \rightarrow R_x \quad W_x & \rightarrow R_x \quad R_x & \rightarrow W_x \quad W_x & \rightarrow W_x \\
    y &= x; \quad x &= 0; \quad y &= x; \quad x &= 0; \\
    z &= x; \quad y &= x; \quad x &= 3; \quad x &= 3; \\
    \end{align*}
    \]

    Which statements cannot be reordered?

- control dependency
  
  1. if ( \( x == 0 \) )
  2. \( y = 1; \)

  Statements cannot be reordered as line 1 determines if 2 is executed.
To achieve better performance, compiler/hardware make changes:

1. reorder disjoint (independent) operations (variables have different addresses)

\[
R_x \rightarrow R_y \quad W_x \rightarrow R_y \quad R_x \rightarrow W_y \quad W_x \rightarrow W_y
\]

\[
t = x; \quad x = 0; \quad x == 1; \quad y = 0;
\]

\[
s = y; \quad y == 1; \quad y = 3; \quad x = 3;
\]

Which statements cannot be reordered?

2. elide unnecessary operations (transformation/dead code)

\[
x = 0; \quad // unnecessary, immediate change
\]

\[
x = 3;
\]

\[
\text{for} \ ( \text{int} \ i = 0; \ i < 10000; \ i += 1) \ ); \quad // unnecessary, no loop body
\]

\[
\text{int} \ \text{factorial}( \text{int} \ n, \ \text{int} \ acc ) \{ \quad // \text{tail recursion}
\]

\[
\text{if} \ (n == 0) \ \text{return} \ acc;
\]

\[
\text{return} \ \text{factorial}( n - 1, n \times acc ); \quad // \text{convert to loop}
\]

3. execute in parallel if multiple functional-units (adders, floating units, pipelines, cache)

- Very complex reordering, reducing, and overlapping of operations allowed.

- Overlapping implies parallelism, but limited capability in sequential execution.

### 10.2 Memory Hierarchy

Complex memory hierarchy:

- Optimizing data flow along this hierarchy defines a computer’s speed.

- Hardware aggressively optimizes data flow for sequential execution.

- Having basic understanding of cache is essential to understanding performance of both sequential and concurrent programs.
10.2.1 Cache Review

- Problem: CPU 100(0) times faster than memory (100,00(0) times faster than disk).

- Solution: copy data from general memory into very, very fast local-memory (registers).

- Problem: billions of bytes of memory but only 6–256 registers.

- Solution: move highly accessed data within a program from memory to registers for as long as possible and then back to memory.

- Problem: quickly run out of registers as more data accessed.
  - ⇒ must rotate data from memory through registers dynamically.
  - compiler attempts to keep highly used variables in registers (LRU, requires oracle)

- Problem: does not handle highly accessed data among programs (threads).
  - each context switch saves and restores most registers to memory

- Solution: use hardware cache (automatic registers) to stage data without pushing to memory and allow sharing of data among programs.

```c
int x, y, z;
x += 1;  // load register 1 from x
add r1,#1  // increment
st r1,0xa3480  // store register 1 to x
```

- Caching transparently hides the latency of accessing main memory.
- Cache loads in 64/128/256 bytes, called cache line, with addresses multiple of line size.
When \( x \) is loaded into register 1, a cache line containing \( x, y, \) and \( z \) are implicitly copied up the memory hierarchy from memory through caches.

- When cache is full, data evicted, i.e., remove old cache-lines to bring in new (LRU).
- When program ends, its addresses are flushed from the memory hierarchy.

- In theory, cache can eliminate registers, but registers provide small addressable area (register window) with short addresses (3-8 bits for 8-256 registers) ⇒ shorter instructions.

### 10.2.2 Cache Coherence

- Multi-level caches used, each larger but with diminishing speed (and cost).
- E.g., 64K L1 cache (32K Instruction, 32K Data) per core, 256K L2 cache per core, and 8MB L3 cache shared across cores.

- Data reads logically percolate variables from memory up the memory hierarchy, making cache copies, to registers.

- Why is it necessary to eagerly move reads up the memory hierarchy?

- Data writes from registers to variables logically percolate down the memory hierarchy through cache copies to memory.

- Why is it advantageous to lazily move writes down the memory hierarchy?

- If OS moves program to another processor, all caching information is invalid and the program’s data-hierarchy reforms.
• Unlike registers, all cache values are shared across the computer.
• Hence, variable can be replicated in a large number of locations.
• No cache coherence for shared variable \( x \) (madness)

\[
\begin{array}{ccc}
\text{core} & \text{processor}_1 & \text{processor}_2 \\
\text{registers} & \begin{array}{c} T_1 \\ 16 \\ 16 \\
12 \\ 1 
\end{array} & \begin{array}{c} T_2 \\ 34 \\ 34 \\
4 \\ 3 
\end{array} \\
\text{L1} & \begin{array}{c} 16 \\ 90 \\
90 \\
90 \\ 90 
\end{array} & \begin{array}{c} 34 \\ 90 \\
90 \\
90 \\ 90 
\end{array} \\
\text{L2} & \begin{array}{c} 12 \\ 90 \\
90 \\
90 \\ 90 
\end{array} & \begin{array}{c} 4 \\ 90 \\
90 \\
90 \\ 90 
\end{array} \\
\text{L3} & \begin{array}{c} 1 \\ 90 \\
90 \\
90 \\ 90 
\end{array} & \begin{array}{c} 3 \\ 90 \\
90 \\
90 \\ 90 
\end{array} \\
\text{memory} & x & 90
\end{array}
\]

• With cache coherence for shared variable \( x \)

\[
\begin{array}{ccc}
\text{core} & \text{processor}_1 & \text{processor}_2 \\
\text{registers} & \begin{array}{c} T_1 \\ 16 \\ 90 \\
90 \\ 90 \\
90 \\ 90 
\end{array} & \begin{array}{c} T_2 \\ 34 \\ 90 \\
90 \\
90 \\ 90 
\end{array} \\
\text{L1} & \begin{array}{c} 16 \\ 34 \\
90 \\
90 \\
90 \
\end{array} & \begin{array}{c} 90 \\ 90 \\
90 \\
90 \\ 90 
\end{array} \\
\text{L2} & \begin{array}{c} 12 \\ 90 \\
90 \\
90 \\
90 
\end{array} & \begin{array}{c} 4 \\ 90 \\
90 \\
90 \\
90 
\end{array} \\
\text{L3} & \begin{array}{c} 1 \\ 90 \\
90 \\
90 \\
90 
\end{array} & \begin{array}{c} 3 \\ 90 \\
90 \\
90 \\
90 
\end{array} \\
\text{memory} & x & 90
\end{array}
\]

• Cache coherence is hardware protocol ensuring update of duplicate data.
• Cache consistency addresses when processor sees update ⇒ bidirectional synchronization.

\[
\begin{array}{c}
\text{Core 1} \\
\text{L1} 0xa34d0 \text{ update}
\end{array}
\quad
\begin{array}{c}
\text{Core N} \\
\text{L1} 0xa34d0 \text{ invalid}
\end{array}
\]

• Eager cache-consistency means data changes appear instantaneous by waiting for acknowledge from all cores (complex/expensive).
• Lazy cache-consistency allows reader to see own write before acknowledgement ⇒ concurrent programs read stale data!
  o writes eventually appear in (largely) same over as written
  o critical section works as writes to shared variable appear before write to lock release
  o otherwise, spin (lock) until write appears

• If threads continually read/write same memory locations, they invalidate duplicate cache lines, resulting in excessive cache updates.
  o called cache thrashing
  o updated value bounces from one cache to the next

• Because cache line contains multiple variables, cache thrashing can occur inadvertently, called false sharing.

• Thread 1 read/writes x while Thread 2 read/writes y ⇒ no direct shared access, but indirect sharing as x and y share cache line.
  o Fix by separating x and y with sufficient storage (padding) to be in next cache line.
  o Difficult for dynamically allocated variables as memory allocator positions storage.

    thread 1
    int *x = new int

    thread 2
    int *y = new int;

  x and y may or may not be on same cache line.

10.3 Concurrent Optimizations

• In sequential execution, strong memory ordering: reading always returns last value written.

• In concurrent execution
  o weak memory ordering: reading can return previously written value or value written in future.
    * happens on multi-processor because of scheduling and buffering (see scrambling/-flickering in Section 5.18.6, p. 84 and freshness/staleness in Section 6.4.4.4, p. 123).
  o notion of current value becomes blurred for shared variables unless everyone can see values assigned simultaneously.

• SME control order and speed of execution, otherwise non-determinism causes random results or failure (e.g., race condition, Section 7.1, p. 133).

• Sequential sections accessing private variables can be optimized normally but not across concurrent boundaries.

• Concurrent sections accessing shared variables can be corrupted by sequential optimizations ⇒ restrict optimizations to ensure correctness.
• For correctness and performance, identify concurrent code and only restrict its optimization.

• What/how to restrict depends on what sequential assumptions are implicitly applied by hardware and compiler (programming language).

• Following examples show how sequential optimizations cause failures in concurrent code.

### 10.3.1 Disjoint Reordering

• $R_x \rightarrow R_y$ allows $R_y \rightarrow R_x$

Reordering disjoint reads does not cause problems. Why?

• $W_x \rightarrow R_y$ allows $R_y \rightarrow W_x$

  ○ In Dekker entry protocol (see Section 5.18.6, p. 84)

  ```
  1. me = WantIn; // W
  2. while ( you == WantIn ) { // R
     3. . . .
  }
  4. temp = you; // R
  5. me = WantIn; // W
  6. while ( temp == WantIn ) {
     7. . . .
  }
  
  both threads read Don'tWantIn, both set WantIn, both see Don'tWantIn, and proceed.
  ```

• $R_x \rightarrow W_y$ allows $W_y \rightarrow R_x$

  ○ In synchronization flags (see Section 5.12, p. 78), allows interchanging lines 1 & 3 for Cons:

  ```
  1. while ( ! Insert ); // R
  2. Insert = false;
  3. data = Data; // W
  4. me = WantIn; // W
  5. ::Last = &me;
  ```

  allows reading of uninserted data

• $W_x \rightarrow W_y$ allows $W_y \rightarrow W_x$

  ○ In synchronization flags (see Section 5.12, p. 78), allows interchanging lines 1 & 2 in Prod and lines 3 & 4 in Cons:

  ```
  1. Data = i; // W
  2. Insert = true; // W
  3. Insert = false;
  4. Data = i; // W
  5. me = WantIn; // W
  6. ::Last = &me;
  ```

  allows reading of uninserted data

  ○ In Peterson’s entry protocol, allows interchanging lines 1 & 2 (see Section 5.18.7, p. 86):

  ```
  1. me = WantIn; // W
  2. ::Last = &me; // W
  3. me = WantIn; // W
  4. ::Last = &me;
  ```

  allows race before either task sets its intent and both proceed
• Compiler uses all of these reorderings to break mutual exclusion:

\[
\text{lock.acquire()} \quad \text{// critical section} \quad \text{lock.acquire()}
\]
\[
\text{// critical section} \quad \text{lock.acquire()} \quad \text{lock.release()};
\]
\[
\text{lock.release();} \quad \text{lock.release();} \quad \text{// critical section}
\]

- moves lock entry/exit after/before critical section because entry/exit variables not used in critical section.

10.3.2 Eliding

• For high-level language, compiler decides when/which variables are loaded into registers.

• Elide reads (loads) by copying (replicating) value into a register:

\[
\text{Task}_1 \quad \ldots \quad \text{flag} = \text{false} \quad \text{// write} \quad \text{while ( register );} \quad \text{// cannot see change by } T_1
\]

• Hence, variable logically disappears for duration in register.

• ⇒ task spins forever in busy loop if R before W.

• Also, elide meaningless sequential code:

\[
\text{sleep( 1 );} \quad \text{// unnecessary in sequential program}
\]

⇒ task misses signal by not delaying

10.3.3 Replication

• Why is there a benefit to reorder R/W?

• Modern processors increase performance by executing multiple instructions in parallel (data flow, precedence graph (see 6.4.1)).

  - internal pool of instructions taken from program order
  - begin simultaneous execution of instructions with inputs
  - collect results from finished instructions
  - feed results back into instruction pool as inputs
  - ⇒ instructions with independent inputs execute out-of-order

• From sequential perspective, disjoint reordering is unimportant, so hardware starts many instruction simultaneously.

• From concurrent perspective, disjoint reordering is important.
• E.g., **double-check locking** for singleton-pattern:

```c
int * ip = nullptr; // volatile for correctness

if ( ip == nullptr ) { // no storage ?
    lock.acquire(); // attempt to get storage (race)
    if ( ip == nullptr ) { // still no storage? (double check)
        ip = new int( 0 ); // obtain and initialize storage
    }
    lock.release();
}
```

Why do the first check? Why do the second check?

• Fails if last two writes are reordered, \( W_{malloc} \) and \( W_{ip} \), disjoint variables:

```c
call malloc
st #0,(r1) // new storage address returned in r1
st r1,ip // initialize storage
```

see \( ip \) but uninitialized.

## 10.4 Memory Model

• Manufactures define set of optimizations performed implicitly by processor.

• Set of optimizations indirectly define a **memory model**.

<table>
<thead>
<tr>
<th>Relaxation Model</th>
<th>W → R</th>
<th>R → W</th>
<th>W → W</th>
<th>Lazy cache update</th>
</tr>
</thead>
<tbody>
<tr>
<td>atomic consistent (AT)</td>
<td></td>
<td></td>
<td></td>
<td></td>

</table>

• AT has events occur instantaneously ⇒ slow or impossible (distributed).

• SC accepts all events cannot occur instantaneously ⇒ may read old values

• SC still strong enough for software mutual-exclusion (Dekker 5.18.6 / Peterson 5.18.7).
  ○ SC often considered minimum model for concurrency (Java provides SC)

• No hardware supports just AT/SC.
  ○ TSO (x86/SPARC), PSO (ARM), WO (Alpha), RC (PowerPC)
10.5 Preventing Optimization Problems

- All optimization problems result from races on shared variables.

- If shared data is protected by locks (implicit or explicit),
  - locks define the sequential/concurrent boundaries,
  - boundaries must preclude optimizations that affect concurrency.

- Called race free as synchronization and mutual exclusion preclude races.

- However, race free does mean there are no races.

- Races are internal to locks, which lock programmer must deal with.

- Two approaches:
  - ad hoc: programmer manually augments all data races with pragmas to restrict compiler/hardware optimizations: not portable but often optimal.
  - formal: language has memory model and mechanisms to abstractly define races in program: portable but often baroque and suboptimal.

- data access / compiler (C/C++): volatile qualifier
  - Force variable loads and stores to/from registers (at sequence points)
  - created for longjmp or force access for memory-mapped devices
  - for architectures with few registers, practically all variables are implicitly volatile. Why?
  - Java volatile / C++11 atomic stronger ⇒ prevent eliding and disjoint reordering.

- program order / compiler (static): disable inlining, asm(" :: "memory");

- memory order / runtime (dynamic): sfence, lfence, mfence (x86)
  - guarantee previous stores and/or loads are completed, before continuing.

- atomic operations test-and-set, which often imply fencing

- cache is normally invisible and does not cause issues (except for DMA)

- mechanisms to fix issues are specific to compiler or platform
  - difficult, low-level, diverse semantics, not portable ⇒ tread carefully!

- Dekker for TSO:
```c
#define CALIGN __attribute__(( aligned (64) )) // cache-line alignment
#define Fence() __asm__ __volatile__ ( "mfence" ) // prevent hardware reordering
#define Pause() __asm__ __volatile__ ( "pause" : : ) // efficient busy wait

enum Intent { DontWantIn, WantIn } Last;
_Task Dekker {
  volatile Intent &me, &you, *&Last;
  void main() {
    for ( int i = 1; i <= 1000; i += 1 ) {
      for ( ;; ) {
        // entry protocol
        me = WantIn; // high priority
        Fence();
        if ( you == DontWantIn ) break;
        if ( Last == &me ) { // high priority ?
          me = DontWantIn;
          Fence();
          while ( Last == &me ) Pause(); // low priority
        }
        Pause();
    }
    CriticalSection(); // critical section
    Last = &me; // exit protocol
    me = DontWantIn;
  }
}

public:
Dekker( volatile Intent &me, volatile Intent &you, volatile Intent *&Last ) :
  me(me), you(you), Last(Last) {}
};

int main() {
  volatile Intent me CALIGN = DontWantIn, you CALIGN = DontWantIn,
  *Last CALIGN = rand() % 2 ? &me : &you;
  Dekker t0(me, you, Last), t1(you, me, Last);
};
```

- Locks built with these features ensure SC for protected shared variables.
  - no user races and strong locks ⇒ SC memory model
11 Other Approaches

11.1 Atomic (Lock-Free) Data-Structure

- **Lock free** data-structure have operations, which are critical sections, but performed without ownership.
  - e.g., add/remove node without any blocking duration (operation takes constant atomic time)

- Lock-free is still locking (misnomer) ⇒ spin for conceptual lock ⇒ starvation.

- If guarantees individual progress, called **wait free**.

11.1.1 Compare and Assign Instruction

- The compare-and-assign(set) instruction performs an atomic compare and conditional assignment CAA (erroneously called compare-and-swap, CAS).

```c
int Lock = OPEN; // shared

bool CAA( int & val, int comp, int nval ) {
  // begin atomic
  if ( val == comp ) {
    val = nval;
    return true;
  }
  return false;
  // end atomic
}

void Task::main() { // each task does
  while ( ! CAA( Lock, OPEN, CLOSED ) );
    // critical section
    Lock = OPEN;
}
```

  - if compare/assign returns true ⇒ loop stops and lock is set to closed
  - if compare/assign returns false ⇒ loop executes until the other thread sets lock to open
  - Alternative implementation assigns comparison value with the value when not equal.

```c
bool CAV( int & val, int & comp, int nval ) {
  // begin atomic
  if (val == comp) {
    val = nval;
    return true;
  }
  comp = val; // return changed value
  return false;
  // end atomic
}
```

  - Assignment when unequal useful to restart operations with new changed value.
11.1.2 Lock-Free Stack

- E.g., build a stack with lock-free push and pop operations.

```cpp
class Stack {
    Node * top; // pointer to stack top

public:
    struct Node {
        // data
        Node * next; // pointer to next node
    };
    void push( Node & n );
    Node * pop();
};
```

- Use CAA to atomically update top pointer when nodes pushed or popped concurrently.

```cpp
void Stack::push( Node & n ) {
    for ( ;; ) { // busy wait
        n.next = top; // link new node to top node
        if ( CAA( top, n.next, &n ) ) break; // attempt to update top node
    }
}
```

- Create new node, n, at 0x4ffb8 to be added.
- Set n.next to top.
- CAA tries to assign new top &n to top.
- CAA fails if top changed since copied to n.next
- If CAA failed, update n.next to top, and try again.
- CAA succeeds when top == n.next, i.e., no push or pop between setting n.next and trying to assign &n to top.
- CAV copies changed value to n.next, so eliminates resetting t = top in busy loop.
Node * Stack::pop() {
    Node * t;
    for ( ;; ) { // busy wait
        t = top; // copy current top
        if ( t == nullptr ) return t; // empty list ?
        if ( CAA( top, t, t->next ) ) return t; // attempt to update top node
    }
}

○ Copy top node, 0x4fbb8, to t for removal.
○ If not empty, attempt CAA to set new top to next node, t->next.
○ CAA fails if top changed since copied to t.
○ If CAA failed, update t to top, and try again.
○ CAA succeeds when top == t->next, i.e., no push or pop between setting t and trying to assign t->next to top.
○ CAV copies the changed value into t, so eliminates resetting t = top in busy loop.

• Note, speculative load of top->next can access stolen node and fail if storage freed, and address-space shortened.

11.1.3 ABA problem

• Pathological failure for series of pops and pushes, called ABA problem.

• Given stack with 3 nodes:
    top → A → B → C

• Popping task, $T_i$, sets t to A and dereferenced t->next to get next node B for argument to CAA.

• $T_i$ is now time-sliced before the CAA, and while blocked, nodes A and B are popped, and A is pushed again:
    top → A → C // B is gone!

• When $T_i$ restarts, CAA successfully removes A as same header before time-slice.
• But now incorrectly sets top to its next node B:
  
  top → B → ???

  stack is now corrupted!!!

11.1.4 Hardware Fix

• Probabilistic solution for stack exists using double-wide CAVD instruction, which compares and assigns 64/128-bit values for 32/64-bit architectures.

  bool CAVD( uintS_t &val, uintS_t &comp, uintS_t nval ) {
    // begin atomic
    if ( val == comp ) {
      // 64/128-bit compare
      val = nval;
      // 64/128-bit assignment
      return true;
    }
    comp = val;
    // 64/128-bit assignment
    return false;
    // end atomic
  }

• Now, associate counter (ticket) with header node:

  class Stack {
    union Link {
      struct {
        // 32/64-bit x 2
        Node * top;  // pointer to stack top
        uintptr_t count;  // count each push
      };
      uintS_t atom;  // 64/128-bit integer
    } link;
  public:
    struct Node {
      // resource data
      Link next;  // pointer to next node/count (resource)
    };
  Stack() { link.atom = 0; }
  void push( Node & n );
  Node * pop();

  };

• Increment counter in push so pop can detect ABA if node re-pushed.

  void Stack::push( Node & n ) {
    n.next = link;  // atomic assignment unnecessary
    for ( ;; ) {
      // busy wait
      if ( CAVD( link.atom, n.next.atom,
                 (Link){ &n, n.next.count + 1 }.atom ) ) break;
    }
  }

  CAVD used to copy entire header to n.next, as structure assignment (2 fields) is not atomic.
In busy loop, copy local idea of top to next of new node to be added.

CAVD tries to assign new top-header to \( h \).

If top has not changed since copied to \( n.next \), update top to \( n \) (new top), and \textit{increment counter}.

If top has changed, CAVD copies changed values to \( n.next \), so try again.

Node * Stack::pop() {
    Link t = link; // atomic assignment unnecessary
    for ( ;; ) { // busy wait
        if ( t.top == nullptr ) return nullptr; // empty stack?
        if ( CAVD( link.atom, t.atom,
                    (Link){ t.top->next.top, t.count }.atom ) ) return t.top;
    }
}

CAVD used to copy entire header to \( t \), as structure assignment (2 fields) is not atomic.

In busy loop, check if pop on empty stack and return \texttt{nullptr}.

If not empty, CAVD tries to assign new top \( t.top->next.top, t.count \) to \( h \).

If top has not changed since copied to \( t \), update top to \( t.top->next.top \) (new top).

If top has changed, CAVD copies changed values to \( t \), so try again.

\phantomsection
\addcontentsline{toc}{section}{ABA problem (mostly) fixed:}

\begin{itemize}
    \item top,3 \rightarrow A \rightarrow B \rightarrow C
\end{itemize}

Popping task, \( T_i \), has \( t \) set to A,3 and dereferenced B from \( t.top->next \) in argument of CAVD.

\( T_i \) is time-sliced, and while blocked, nodes A and B are popped, and A is pushed again:

\begin{itemize}
    \item top,4 \rightarrow A \rightarrow C \quad // adding A increments counter
\end{itemize}

When \( T_i \) restarts, CAVD fails as header A,3 not equal top A,4.

Only probabilistic correct as counter finite (like ticket counter).

\begin{itemize}
    \item task \( T_i \) is time-sliced and sufficient pushes wrap counter to value stored in \( T_i \)’s header,
    \item node A just happens to be at the top of the stack when \( T_i \) unblocks.
    \item doubtful if failure arises, given 32/64-bit counter and pathological case.
\end{itemize}

Finally, none of the programs using CAA ensure eventual progress; therefore, rule 5 is broken.
11.1.5 Hardware/Software Fix

- Fixing ABA with CAA/V and more code is extremely complex (100s of lines of code), as is implementing more complex data structures (queue, deque, hash).

- All solutions require complex determination of when a node has no references (like garbage collection).
  - each thread maintains a list of accessed nodes, called hazard pointers
  - thread updates its hazard pointers while other threads are reading them
  - thread removes a node by hiding it on a private list and periodically scans the hazard lists of other threads for referencing to that node
  - if no pointers are found, the node can be freed

- For lock-free stack: x, y, z are memory addresses
  - first thread puts x on its hazard list
  - second thread cannot reuse x, because of hazard list
  - second thread must create new object at different location
  - first thread detects change

- Summary: locks versus lock-free
  - lock-free has no ownership (hold-and-wait) ⇒ no deadlock
  - lock can protect arbitrarily complex critical section versus lock-free can only handle limited set of critical sections
  - lock-free no panacea, performance unclear
  - combine lock and lock-free?

11.2 Exotic Atomic Instruction

- VAX computer has instructions to atomically insert and remove a node to/from the head or tail of a circular doubly linked list.

```c
struct links {
    links *front, *back;
};

bool INSQUE( links &entry, links &pred ) {    // atomic execution
    return entry.front == entry.back;       // first node inserted ?
}

bool REMQUE( links &entry ) {               // atomic execution
    return entry.front == null;             // last node removed ?
}
```
MIPS processor has two instructions that generalize atomic read/write cycle: LL (load locked) and SC (store conditional).

- LL instruction loads (reads) a value from memory into a register, and sets a hardware reservation on the memory from which the value is fetched.
- Register value can be modified, even moved to another register.
- SC instruction stores (writes) new value back to original or another memory location.
- However, store is conditional and occurs only if no interrupt, exception, or write has occurred at LL reservation.
- Failure indicated by setting the register containing the value to be stored to 0.
- E.g., implement test-and-set with LL/SC:

```c
int testSet( int &lock ) {   // atomic execution
    int temp = lock;       // read
    lock = 1;              // write
    return temp;           // return previous value
}
```

- Does not suffer from ABA problem.

```c
Node *pop( Header &h ) {
    Node *t, next;
    for ( ;; ) {            // busy wait
        t = LL( top );
        if ( t == nullptr ) break; // empty list ?
        next = t->next;
        if ( SC( top, next ) ) break; // attempt to update top node
    }
    return t;
}
```

- SC detects change to top instead of indirect check if value in top changes (CAA).
- However, most architectures support weak LL/SC.
  * reservation granularity may be cache line or memory block rather than word
  * no nesting or interleaving of LL/SC pairs, and prohibit memory access between LL and SC.
- Cannot implement atomic swap of 2 memory location as two reservations are necessary (register to memory swap is possible).

- Hardware transactional memory allows 4, 6, 8 reservations, e.g., Advanced Synchronization Facility (ASF) proposal in AMD64.
Like database **transaction** that optimistically executes change, and either commits changes, or rolls back and restarts if interference.

- **SPECULATE**: start speculative region and clear zero flag; next instruction checks for abort and branches to retry.
- **LOCK**: MOV instructions indicates location for atomic access, but moves not visible to other CPUs.
- **COMMIT**: end speculative region
  - if no conflict, make MOVs visible to other CPUs.
  - if conflict to any move locations, set failure, discard reservations and restore registers back to instruction following SPECULATE
- Can implement several data structures without ABA problem.

Software Transactional Memory (STM) allows any number of reservations.

- atomic blocks of arbitrary size:
  ```c
  void push( header & h, node & n ) {
      atomic {
          n.next = top; // SPECULATE
          top = &n; // LOCK/MOV
      } // COMMIT
  }
  ```
  - records all memory locations read and written, and all values mutated.
    - bookkeeping costs and rollbacks typically result in performance degradation
  - alternative implementation inserts locks to protect shared access
    - finding all access is difficult and ordering lock acquisition is complex

### 11.3 General-Purpose GPU (GPGPU)

- Graphic Processing Unit (GPU) is a **coprocessor** to main computer, with separate memory and processors.

- GPU is a Single-Instruction Multiple-Data(Thread) (SIMD(T)) architecture versus Multiple-Instruction Multiple-Data (MIMD)
11.3. GENERAL-PURPOSE GPU (GPGPU)

- In branching code
  
  ```cpp
  if ( a[i] % 2 == 0 ) {
    a[i] /= 2; // true threads
  }
  else {
    a[i] += 3; // false threads
  }
  ```

  - all threads test the condition (create mask of true and false)
  - true threads execute instructions
  - false threads execute NOP (no-operation)
  - negate mask
  - false threads execute instructions
  - true threads execute NOP

- In general, critical path is time to execute both clauses of if (no speedup).

- Complex contortions to eliminate different forms of branching.

- GPU structure
  
  - **kernel** manages multiple blocks (loaded/controlled by CPU)
  - **block** executes the same code
  - **warp** synchronizes execution (one instruction decoder per warp)
  - **thread** computes value

  ![GPU Architecture Diagram](image)

  - blocks may be barrier-synchronized
  - synchronization among blocks ⇒ finishing kernel and launching new one

- Instead of cache to optimize latency in warp, large register file is used to optimize throughput.
  
  - GPUs have enough duplicate registers to store state of several warps.
• Kernel is memory-bound ⇒ data layout extremely important performance consideration.

```c
#include <stdio.h>

// kernel void GPUSum( float *matrix[], float subtotals[], int rows ) {
    # define sub(m, r, c) ((typeof(m[0][0]) *)m)[r * rows + c]
    subtotals[ID] = 0.0;
    for ( int r = 0; r < rows; r += 1 )
        subtotals[ID] += sub( matrix, r, ID );
}
```

• Add rows by columns.

• Warps scheduled to run when their required data is loaded from memory.

• CPU sets up GPU memory, loads memory, launches code, retrieves results.

```c
int main() {
    int rows, cols;
    cin >> rows >> cols;  // matrix size
    // optimal to use contiguous matrix
    float matrix[rows][cols], subtotals[rows], total = 0.0;
    // ... fill matrix
    float * matrix_d, * subtotals_d;  // matrix/subtotals buffer on GPU
    // allocate space on GPU
    GPUMalloc( &matrix_d, sizeof(matrix) );
    GPUMalloc( &subtotals_d, sizeof(subtotals) );
    // copy matrix to GPU
    GPUMemcpy( matrix_d, matrix, sizeof(matrix), GPUMemcpyHostToDevice );
    // compute matrix sum on GPU
    GPUSum<<< 1, cols >>>( matrix_d, subtotals_d, rows );
    // do asynchronous work!!!
    // copy subtotals from GPU, may block
    GPUMemcpy( subtotals, subtotals_d, sizeof(subtotals), GPUMemcpyDeviceToHost );
    for ( int i = 0; i < cols; i += 1 ) total += subtotals[i];
    cout << total << endl;
}
```

• Most modern multi-core CPUs have similar model using vector-processing.

  ○ Simulate warps and use concurrency framework (μC++) to schedule blocks.
11.4 Concurrency Languages

11.4.1 Ada 95

- E.g., monitor bounded-buffer, restricted implicit (automatic) signal:

```ada
protected type buffer is -- _Monitor
  entry insert( elem : in ElemType ) when count < Size is -- mutex member
  begin -- add to buffer
    count := count + 1;
  end insert;
  entry remove( elem : out ElemType ) when count > 0 is -- mutex member
  begin -- remove from buffer, return via parameter
    count := count - 1;
  end remove;
private:
  . . . // buffer declarations
  count : Integer := 0;
end buffer;
```

- The `when` clause is only be used at start of entry routine not within.

- The `when` expression can contain only global-object variables; parameter or local variables are disallowed ⇒ no direct dating-service.

- Eliminate restrictions and dating service is solvable.

```ada
  __Monitor DatingService { 
  AUTOMATIC_SIGNAL;
  int girls[noOfCodes], boys[noOfCodes]; // count girls/boys waiting
  bool exchange; // performing phone-number exchange
  int girlPhoneNo, boyPhoneNo; // communication variables
public:
  int girl( int phoneNo, int ccode ) { 
    girls[ccode] += 1;
    if ( boys[ccode] == 0 ) { // no boy waiting ?
      WAITUNTIL( boys[ccode] != 0, , ); // use parameter, not at start
      boys[ccode] -= 1; // decrement dating pair
      girls[ccode] -= 1;
      girlPhoneNo = phoneNo; // girl's phone number for exchange
      exchange = false; // wake boy
    } else {
      girlPhoneNo = phoneNo; // girl's phone number before exchange
      exchange = true; // start exchange
      WAITUNTIL( ! exchange, , ); // wait until exchange complete, not at start
    }
    RETURN( boyPhoneNo );
  }
  // boy
};
```
• E.g., task bounded-buffer:

```ada
task type buffer is -- _Task
  ... -- buffer declarations
  count : integer := 0;
begin -- thread starts here (task main)
  loop
    select -- _Accept
      when count < Size => -- guard
        accept insert(elem : in ElemType) do -- mutex member
          -- add to buffer
          count := count + 1;
        end;
        -- executed if this accept called
    or
      when count > 0 => -- guard
        accept remove(elem : out ElemType) do -- mutex member
          -- remove from buffer, return via parameter
          count := count - 1;
        end;
    end select;
  end loop;
end buffer;
var b : buffer -- create a task
```

• `select` is external scheduling and only appear in `task` main.

• Hence, Ada has no direct internal-scheduling mechanism, i.e., no condition variables.

• Instead a `requeue` statement can be used to make a `blocking` call to another (usually non-public) mutex member of the object.

• The original call is re-blocked on that mutex member’s entry queue, which can be subsequently accepted when it is appropriate to restart it.

• However, all `requeue` techniques suffer the problem of dealing with accumulated temporary results:
  
  o If a call must be postponed, its temporary results must be returned and bundled with the initial parameters before forwarding to the mutex member handling the next step,
  
  o or the temporary results must be re-computed at the next step (if possible).

• In contrast, waiting on a condition variable automatically saves the execution location and any partially computed state.

11.4.2 SR/Concurrent C++

• SR and Concurrent C++ have tasks with external scheduling using an `accept` statement.

• But no condition variables or `requeue` statement.

• To ameliorate lack of internal scheduling add a `when` and by clause on the `accept` statement.
11.4. CONCURRENCY LANGUAGES

- **when** clause is allowed to reference caller’s arguments via parameters of mutex member:

```plaintext
select
  accept mem( code : in Integer )
  when code % 2 = 0 do ... -- accept call with even code
or
  accept mem( code : in Integer )
  when code % 2 = 1 do ... -- accept call with odd code
end select;
```

- **when** placed after the **accept** clause so parameter names are defined.

- **when** referencing parameter ⇒ implicit search of waiting tasks on mutex queue ⇒ locking mutex queue.

- Select longest waiting if multiple true **when** clauses.

- **by** clause is calculated for each true **when** clause and the minimum **by** clause is selected.

```plaintext
select
  accept mem( code : in Integer )
  when code % 2 = 0 by -code do ...-- accept largest even code
or
  accept mem( code : in Integer )
  when code % 2 = 1 by code do ...-- accept smallest odd code
end select;
```

- Select longest waiting if multiple **by** clauses with same minimum.

- **by** clause exacerbates the execution cost of computing **accept** clause.

- While **when/by** remove some internal scheduling and/or requeue, constructing expressions can be complex.

- Still situations that cannot be handled, e.g., if selection criteria involves multiple parameters:
  - select lowest even value of code1 and highest odd value of code2 if there are multiple lowest even values.
  - selection criteria involves information from other mutex queues such as the dating service (girl must search the boy mutex queue).

- Often simplest to unconditionally accept a call allowing arbitrarily examination, and possibly postpone (internal scheduling).

11.4.3 Java

- Java’s concurrency constructs are largely derived from Modula-3.
class Thread implements Runnable {
    public Thread();
    public Thread(String name);
    public String getName();
    public void setName(String name);
    public void run();  // uC++ main
    public synchronized void start();
    public static Thread currentThread();
    public static void yield();
    public final void join();
}

• Thread is like µC++ uBaseTask, and all tasks must explicitly inherit from it:

    class MyTask extends Thread {  // inheritance
        private int arg;        // communication variables
        private int result;
        public MyTask() {...}  // task constructors
        public void run() {...}  // task main
        public int result() {...}  // return result
        // unusual to have more members
    }

• Thread starts in member run.

• Java requires explicit starting of a thread by calling start after the thread’s declaration.
  ⇒ coding convention to start thread or inheritance is precluded (can only start a thread once)

• Termination synchronization is accomplished by calling join.

• Returning a result on thread termination is accomplished by member(s) returning values
  from the task’s global variables.

    mytask th = new MyTask(...);  // create and initialized task
    th.start();                    // start thread
    // concurrency
    th.join();                    // wait for thread termination
    a2 = th.result();            // retrieve answer from task object

• Like µC++, when the task’s thread terminates, it becomes an object, hence allowing the call
  to result to retrieve a result.

• (see Section 8.8, p. 155 for monitors)

• While it is possible to have public synchronized members of a task:
  o no mechanism to manage direct calls, i.e., no accept statement
  o ⇒ complex emulation of external scheduling with internal scheduling for direct communication
11.4. CONCURRENCY LANGUAGES

11.4.4 Go

- Non-object-oriented, light-weight (like \(\mu\text{C++}\)) non-preemptive? threads (called goroutine).
  - \(\Rightarrow\) busy waiting only on multicore (Why?)

- go statement (like start/fork) creates new user thread running in routine.
  
  ```go
  go foo( 3, f )    // start thread in routine foo
  ```

- Arguments may be passed to goroutine but return value is discarded.

- Cannot reference goroutine object \(\Rightarrow\) no direct communication.

- All threads terminate silently when program terminates.

- Threads synchronize/communicate via channel (CSP)
  - \(\Rightarrow\) paradigm shift from routine call.

- Channel is a typed shared buffer with 0 to N elements.

  ```go
  ch1 := make( chan int, 100 )    // integer channel with buffer size 100
  ch2 := make( chan string )      // string channel with buffer size 0
  ch2 := make( chan chan string ) // channel of channel of strings
  ```

- Buffer size \(> 0 \Rightarrow\) up to N asynchronous calls; otherwise, synchronous call.

- Operator \_<\_> performs send/receive.
  - send: \(ch1 \_<\_> 1\)
  - receive: \(s \_<\_> ch2\)

- Channel can be constrained to only send or receive; otherwise bi-directional.
package main

import "fmt"

func main() {

type Msg struct{ i, j int }

ch1 := make(chan int)
ch2 := make(chan float32)
ch3 := make(chan Msg)
hand := make(chan string)
shake := make(chan string)

gortn := func() {
    var i int;
    var f float32;
    var m Msg

    L:
    for {
        select {
            // wait for message
            case i = <- ch1: fmt.Println(i)
            case f = <- ch2: fmt.Println(f)
            case m = <- ch3: fmt.Println(m)
            case <- hand: break L // sentinel
        }
    }

    shake <- "SHAKE" // completion
}

go gortn() // start thread in gortn

ch1 <- 0 // different messages
ch2 <- 2.5
ch3 <- Msg{1, 2}

hand <- "HAND" // sentinel value

<--shake // wait for completion
}

}
// wait for completion

• Locks
11.4. CONCURRENCY LANGUAGES

- Atomic operations

  ```go
  func AddInt32(val *int32, delta int32) (new int32)
  func AddInt64(val *int64, delta int64) (new int64)
  func AddUint32(val *uint32, delta uint32) (new uint32)
  func AddUint64(val *uint64, delta uint64) (new uint64)
  func AddUintptr(val *uintptr, delta uintptr) (new uintptr)
  func CompareAndSwapInt32(val *int32, old, new int32) (swapped bool)
  func CompareAndSwapInt64(val *int64, old, new int64) (swapped bool)
  func CompareAndSwapPointer(val *unsafe.Pointer, old, new unsafe.Pointer) (swapped bool)
  func CompareAndSwapUint32(val *uint32, old, new uint32) (swapped bool)
  func CompareAndSwapUint64(val *uint64, old, new uint64) (swapped bool)
  func CompareAndSwapUintptr(val *uintptr, old, new uintptr) (swapped bool)
  func LoadInt32(addr *int32) (val int32)
  func LoadInt64(addr *int64) (val int64)
  func LoadPointer(addr *unsafe.Pointer) (val unsafe.Pointer)
  func LoadUint32(addr *uint32) (val uint32)
  func LoadUint64(addr *uint64) (val uint64)
  func LoadUintptr(addr *uintptr) (val uintptr)
  func StoreInt32(addr *int32, val int32)
  func StoreInt64(addr *int64, val int64)
  func StorePointer(addr *unsafe.Pointer, val unsafe.Pointer)
  func StoreUint32(addr *uint32, val uint32)
  func StoreUint64(addr *uint64, val uint64)
  func StoreUintptr(addr *uintptr, val uintptr)
  ```

11.4.5 C++11 Concurrency

- C++11 library can be sound as C++ now has strong memory-model (SC).

  - compile: `g++ -std=c++11 -lpthread ...`

- Thread creation: start/wait (fork/join) approach.

  ```go
class thread {
  public:
    template <class Fn, class... Args>
    explicit thread( Fn && fn, Args &&... args );
    void join();               // termination synchronization
    bool joinable() const;    // true => joined, false otherwise
    void detach();            // independent lifetime
    id get_id() const;        // thread id
};
```

- Passing multiple arguments uses C++11’s variadic template feature to provide a type-safe call chain via thread constructor to the callable routine.

- Any entity that is callable (functor) may be started:
```cpp
#include <thread>

void hello(const string & s) { // callable
    cout << "Hello " << s << endl;
}

class Hello { // functor
    int result;
    public:
        void operator()(const string & s) { // callable
            cout << "Hello " << s << endl;
        }
};

int main() {
    thread t1(hello, "Peter"); // start thread in routine "hello"
    Hello h; // thread object
    thread t2(h, "Mary"); // start thread in functor "h"
    // work concurrently
    t1.join(); // termination synchronization
    // work concurrently
    t2.join(); // termination synchronization
} // must join before closing block

• Thread starts implicit at point of declaration.

• Instead of join, thread can run independently by detaching:

    t1.detach(); // "t1" must terminate for program to end

• Beware dangling pointers to local variables:

    {
        string s("Fred"); // local variable
        thread t(hello, s);
        t.detach();
    } // "s" deallocated and "t" running with reference to "s"

• It is an error to deallocate thread object before join or detach.

• Locks

    ○ mutex, recursive, timed, recursive-timed

        class mutex {
            public:
                void lock(); // acquire lock
                void unlock(); // release lock
                bool try_lock(); // nonblocking acquire
            
        }

    ○ condition
### 11.4. CONCURRENCY LANGUAGES

```cpp
class condition_variable {
public:
    void notify_one(); // unblock one
    void notify_all(); // unblock all
    void wait( mutex &lock ); // atomically block & release lock
};
```

- Scheduling is no-priority nonblocking ⇒ barging ⇒ wait statements must be in while loops to recheck conditions.

```cpp
#include <mutex>
class BoundedBuffer { // simulate monitor
    // buffer declarations
    mutex mlock; // monitor lock
    condition_variable empty, full;
    void insert( int elem ) {
        mlock.lock();
        while (count == Size) empty.wait( mlock ); // release lock
        // add to buffer
        count += 1;
        full.notify_one();
        mlock.unlock();
    }

    int remove() {
        mlock.lock();
        while( count == 0 ) full.wait( mlock ); // release lock
        // remove from buffer
        count -= 1;
        empty.notify_one();
        mlock.unlock();
        return elem;
    }
};
```

- Futures

```cpp
#include <future>
big_num pi( int decimal_places ) {...}
int main() {
    future<big_num> PI = async( pi, 1200 ); // PI to 1200 decimal places
    // work concurrently
    cout << "PI " << PI.get() << endl; // block for answer
}
```

- Atomic types/operations

```cpp
atomic_flag, atomic_bool, atomic_char, atomic_schar, atomic_uchar, atomic_short, atomic_ushort,
atomic_int, atomic_uint, atomic_long, atomic_ulong, atomic_llong, atomic_ullong, atomic_wchar_t,
atomic_address, atomic<T>
```
typedef struct atomic_itype {
    bool operator!=(int-type) volatile;
    void store(int-type) volatile;
    int-type load() const volatile;
    int-type exchange(int-type) volatile;
    bool compare_exchange(int-type &old_value, int-type new_value) volatile;
    int-type fetch_add(int-type) volatile;
    int-type fetch_sub(int-type) volatile;
    int-type fetch_and(int-type) volatile;
    int-type fetch_or(int-type) volatile;
    int-type fetch_xor(int-type) volatile;
    int-type operator++() volatile;
    int-type operator++(int) volatile;
    int-type operator--() volatile;
    int-type operator--(int) volatile;
    int-type operator+=(int-type) volatile;
    int-type operator-=(int-type) volatile;
    int-type operator&=(int-type) volatile;
    int-type operator|=(int-type) volatile;
    int-type operator^=(int-type) volatile;
} atomic_itype;

11.5 Threads & Locks Library

11.5.1 java.util.concurrent

- Java library is sound because of memory-model and language is concurrent aware.

- Synchronizers: Semaphore (counting), CountDownLatch, CyclicBarrier, Exchanger, Condition, Lock, ReadWriteLock

- Use new locks to build a monitor with multiple condition variables.

```java
class BoundedBuffer {
    // simulate monitor
    // buffer declarations
    final Lock mlock = new ReentrantLock(); // monitor lock
    final Condition empty = mlock.newCondition();
    final Condition full = mlock.newCondition();
    public void insert( Object elem ) throws InterruptedException {
        mlock.lock();
        try {
            while (count == Size) empty.await(); // release lock
            // add to buffer
            count += 1;
            full.signal();
        } finally { mlock.unlock(); } // ensure monitor lock is unlocked
    }
}
```
public Object remove() throws InterruptedException {
    mlock.lock();
    try {
        while (count == 0) full.await(); // release lock
        count -= 1;
        empty.signal();
        return elem;
    } finally {
        mlock.unlock();
    } // ensure monitor lock is unlocked
}

- Condition is nested class within ReentrantLock ⇒ condition implicitly knows its associated (monitor) lock.
- Scheduling is still no-priority nonblocking ⇒ barging ⇒ wait statements must be in while loops to recheck condition.
- No connection with implicit condition variable of an object.
- Do not mix implicit and explicit condition variables.

- Executor/Future:
  - Executor is a server with one or more worker tasks (worker pool).
  - Call to executor submit is asynchronous and returns a future.
  - Future is closure with work for executor (Callable) and place for result.
  - Result is retrieved using get routine, which may block until result inserted by executor.

```java
import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.*;
public class Client {
    public static void main(String[] args) throws InterruptedException, ExecutionException {
        Callable<Integer> work = new Callable<Integer>() {
            public Integer call() {
                // do some work
                return d;
            }
        };
        ExecutorService executor = Executors.newFixedThreadPool(5);
        List<Future<Integer>> futures = new ArrayList<Future<Integer>>();
        for (int f = 0; f < 10; f += 1) {
            futures.add(executor.submit(work));
        }
        for (int f = 0; f < 10; f += 1) {
            System.out.println(futures.get(f).get()); // retrieve result
        }
        executor.shutdown();
    }
}
```
• \( \mu \)C++ also has fixed thread-pool executor.

```cpp
struct Work {  // routine, functor or lambda
    int operator()() {
        // do some work
        return d;
    }
} work;
```

```cpp
int main() {
    uExecutor executor( 5, 5 ); // user, kernel threads
    Future_ISR<int> futures[10];
    for ( unsigned int f = 0; f < 10; f += 1 )
        // pass work to executor and store returned futures
        futures[i] = executor.sendrecv( work );
    for ( unsigned int f = 0; f < 10; f += 1 )
        cout << futures[f]() << endl; // retrieve result
}
```

• Collections: LinkedBlockingQueue, ArrayBlockingQueue, SynchronousQueue, PriorityBlockingQueue, DelayQueue, ConcurrentHashMap, ConcurrentSkipListMap, ConcurrentSkipListSet, CopyOnWriteArrayList, CopyOnWriteArraySet.

  ○ Create threads that interact indirectly through atomic data structures, e.g., producer/consumer interact via LinkedBlockingQueue.

• Atomic Types using compare-and-assign (see Section 11.1.1, p. 191) (i.e., lock-free).

```java
int v;
AtomicInteger i = new AtomicInteger();
  i.set( 1 );
System.out.println( i.get() );  // i += delta
v = i.addAndGet( 1 );
System.out.println( i.get() + " " + v );
  v = i.decrementAndGet();  // --i
System.out.println( i.get() + " " + v );
   v = i.getAndAdd( 1 );    // i += delta
System.out.println( i.get() + " " + v );
   v = i.getAndDecrement();  // i--
System.out.println( i.get() + " " + v );
```

11.5.2 Pthreads

• Several libraries exist for C (pthreads) and \( \mu \)C++ (\( \mu \)C++).

• C libraries built around routine abstraction and mutex/condition locks (“attribute” parameters not shown).
11.5. THREADS & LOCKS LIBRARY

```c
int pthread_create( pthread_t * new_thread_ID, 
                   void * (*start_func)(void *), void * arg );
int pthread_join( pthread_t target_thread, void ** status );
pthread_t pthread_self( void );

int pthread_mutex_init( pthread_mutex_t * mp );
int pthread_mutex_lock( pthread_mutex_t * mp );
int pthread_mutex_unlock( pthread_mutex_t * mp );
int pthread_mutex_destroy( pthread_mutex_t * mp );

int pthread_cond_init( pthread_cond_t * cp );
int pthread_cond_wait( pthread_cond_t * cp, pthread_mutex_t * mutex );
int pthread_cond_signal( pthread_cond_t * cp );
int pthread_cond_broadcast( pthread_cond_t * cp );
int pthread_cond_destroy( pthread_cond_t * cp );
```

- Thread starts in routine `start_func` via `pthread_create`.
  Initialization data is single `void *` value.

- Termination synchronization is performed by calling `pthread_join`.

- Return a result on thread termination by passing back a single `void *` value from `pthread_join`.

```c
void * rtn( void * arg ) { . . . }
int i = 3, r, rc;
pthread_t t;      // thread id
rc = pthread_create( &t, rtn, (void *)i ); // create and initialized task
if ( rc != 0 ) . . . // check for error
   // concurrency
rc = pthread_join( t, &r ); // wait for thread termination and result
if ( rc != 0 ) . . . // check for error
```

- All C library approaches have type-unsafe communication with tasks.
- No external scheduling ⇒ complex direct-communication emulation.
- Internal scheduling is no-priority nonblocking ⇒ barging ⇒ wait statements must be in while loops to recheck conditions

```c
typedef struct {
   // simulate monitor
   // buffer declarations
   pthread_mutex_t mutex;     // mutual exclusion
   pthread_cond_t full, empty; // synchronization
} buffer;

// write your own constructor/destructor
void ctor( buffer * buf ) { // constructor
   . . .
   pthread_mutex_init( &buf->mutex );
   pthread_cond_init( &buf->full );
   pthread_cond_init( &buf->empty );
}
```
```c
void dtor( buffer * buf ) {
    // destructor
    pthread_mutex_lock( &buf->mutex ); // must be mutex
    ...
    pthread_cond_destroy( &buf->empty );
    pthread_cond_destroy( &buf->full );
    pthread_mutex_destroy( &buf->mutex );
}

void insert( buffer * buf, int elem ) {
    pthread_mutex_lock( &buf->mutex );
    while ( buf->count == Size )
        pthread_cond_wait( &buf->empty, &buf->mutex );
    // add to buffer
    buf->count += 1;
    pthread_cond_signal( &buf->full );
    pthread_mutex_unlock( &buf->mutex );
}

int remove( buffer * buf ) {
    pthread_mutex_lock( &buf->mutex );
    while ( buf->count == 0 )
        pthread_cond_wait( &buf->full, &buf->mutex );
    // remove from buffer
    buf->count -= 1;
    pthread_cond_signal( &buf->empty );
    pthread_mutex_unlock( &buf->mutex );
    return elem;
}
```

- Since there are no constructors/destructors in C, explicit calls are necessary to `ctor/dtor` before/after use.
- All locks must be initialized and finalized.
- Mutual exclusion must be explicitly defined where needed.
- Condition locks should only be accessed with mutual exclusion.
- `pthread_cond_wait` atomically blocks thread and releases mutex lock, which is necessary to close race condition on baton passing.

### 11.6 OpenMP

- Shared memory, implicit thread management (programmer hints), 1-to-1 threading model (kernel threads), some explicit locking.
- Communicate with compiler with `#pragma` directives.
  ```c
  #pragma omp ...
  ```
- fork/join model
11.6. OPENMP

- fork: initial thread creates a team of parallel threads (including itself)
- each thread executes the statements in the region construct
- join: when team threads complete, synchronize and terminate, except initial thread which continues

- COBEGIN/COEND: each thread executes different section:

```c
#include <omp.h>
...

int main() {
  int i;
  #pragma omp parallel sections num_threads(4) // fork "4" threads
  {
    // COBEGIN
    #pragma omp section
    { i = 1; } // BEGIN ...
    #pragma omp section
    { p1(5); }
    #pragma omp section
    { p2(7); }
    #pragma omp section
    { p3(9); } // COEND (synchronize)
  }
  // compile: gcc -std=c99 -fopenmp openmp.c -lgomp

- for directive specifies each loop iteration is executed by a team of threads (COFOR)

```c
int main() {
  const unsigned int rows = 10, cols = 10; // sequential
  int matrix[rows][cols], subtotals[rows], total = 0;
  // read matrix
  #pragma omp parallel for // fork "rows" threads
  for (unsigned int r = 0; r < rows; r += 1) {
    // concurrent
    subtotals[r] = 0;
    for (unsigned int c = 0; c < cols; c += 1)
      subtotals[r] += matrix[r][c];
  }
  for (unsigned int r = 0; r < rows; r += 1) // sequential
    total += subtotals[r];
  printf("total:%d\n", total);
  } // main

- In this case, sequential code directly converted to concurrent via #pragma.

- Variables outside section are shared; variables inside are thread private.

- Programmer responsible for sharing in vector/matrix manipulation.

- barrier (also critical section and atomic directives)
int main() {
    #pragma omp parallel num_threads( 4 ) // fork "4" threads
    {
        sleep( omp_get_thread_num() );
        printf( "%d\n", omp_get_thread_num() );
        #pragma omp barrier // wait for all threads to finish
        printf("sync\n");
    }
    printf("sync\n");
}

• Threads sleeps for different times, but all print "sync" at same time.
