## **Virtual and Physical Addresses**

- Physical addresses are provided directly by the machine.
  - one physical address space per machine
  - the size of a physical address determines the maximum amount of addressable physical memory
- Virtual addresses (or logical addresses) are addresses provided by the OS to processes.
  - one virtual address space per process
- Programs use virtual addresses. As a program runs, the hardware (with help from the operating system) converts each virtual address to a physical address.
- The conversion of a virtual address to a physical address is called address translation.

On the MIPS, virtual addresses and physical addresses are 32 bits long. This limits the size of virtual and physical address spaces.

CS350 Operating Systems Fall 2015

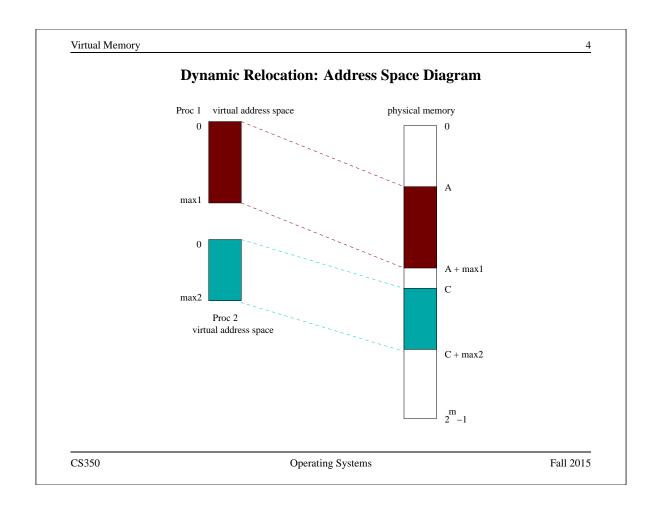

Virtual Memory 2

#### **Simple Address Translation: Dynamic Relocation**

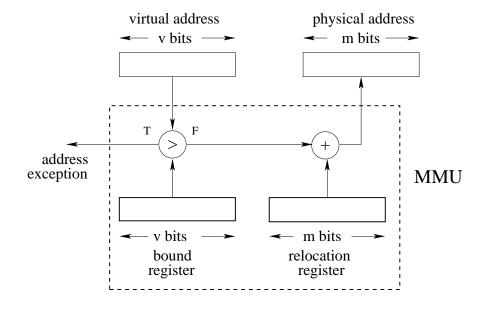

- hardware provides a *memory management unit (MMU)* which includes a *relocation register* and a *limit register* (or *bound register*).
- to translate a virtual address to a physical address, the MMU:
  - checks whether the virtual address is larger than the limit in the limit register
  - if it is, the MMU raises an exception
  - otherwise, the MMU adds the base address (stored in the relocation register) to the virtual address to produce the physical address
- The OS maintains a separate base address and limit for each process, and ensures that the relocation and limit registers in the MMU always contain the base address and limit of the currently-running process.
- To ensure this, the OS must normally change the values in the MMU's registers during each address space switch (i.e., when context switching to a thread of a different process).

## **Properties of Dynamic Relocation**

- each virtual address space corresponds to a *contiguous range of physical addresses*
- the OS is responsible for deciding *where* each virtual address space should map to in physical memory
  - the OS must track which parts of physical memory are in use, and which parts are free
  - since different address spaces may have different sizes, the OS must allocate/deallocate variable-sized chunks of physical memory
  - this creates the potential for external fragmentation of physical memory: wasted, unallocated space
- the MMU is responsible for performing all address translations, using base and limit information provided to it by the the OS

# **Dynamic Relocation Mechanism**

CS350 Operating Systems Fall 2015

Virtual Memory 6

# **Address Translation: Dynamic Relocation Example**

Process 3:	virtual addr		0x000A	1024	
Process 3:	physical addr	=			?

Bound register:

# **Address Translation: Paging**

- Each virtual address space is divided into fixed-size chunks called *pages*
- Physical address space is divided into *frames*. Frame size matches page size.
- OS maintains a *page table* for each process. Page table specifies the frame in which each of the process's pages is located.
- At run time, MMU translates virtual addresses to physical using the page table of the running process.

#### **Properties of Paging**

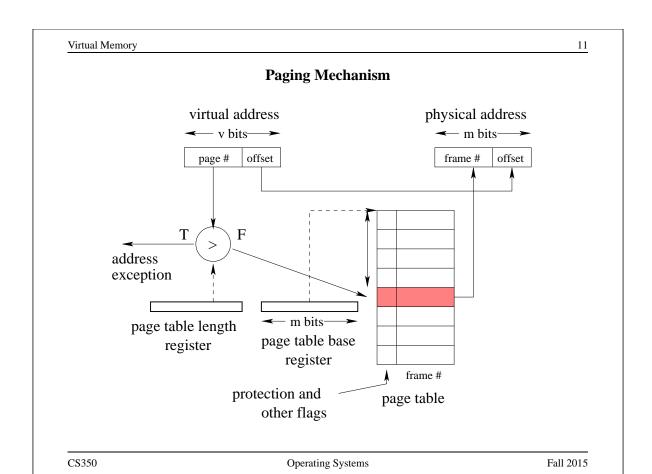

- OS is responsible for deciding which frame will hold each page
  - simple physical memory management
  - potential for *internal fragmentation* of physical memory: wasted, allocated space
  - virtual address space need not be physically contiguous in physical space after translation.
- MMU is responsible for performing all address translations using the page table that is created and maintained by the OS.
- The OS must normally change the values in the MMU registers on each address space switch, so that they refer to the page table of the currently-running process.

CS350 Operating Systems Fall 2015

Virtual Memory 10

#### **How the MMU Translates Virtual Addresses**

- The MMU includes a page table base register and a page table length register.
  - the base register contains the (physical) address of the first page table entry for the currently-running process
  - the length register contains the number of entries in the page table of the currently running process.
- To translate a virtual address, the MMU:
  - determines the *page number* and *offset* of the virtual address
  - checks whether the page number is larger than the value in the page table length register
  - if it is, the MMU raises an exception
  - otherwise, the MMU uses the page table to determine the *frame number* of the frame that holds the virtual page, and combines the frame number and offset to determine the physical address

# **Address Translation: Paging Example**

• Virtual addr = 32 bits, physical addr = 32 bits, offset = 12 bits

Page '	Table Proc 1	Page Table Proc 2			
0x0	010 0000	0x0050 0000			
Page	Frame	Page	Frame		
0	0x5 0002	0	0x4 0001		
1	0x5 0001	1	0x7 9005		
2	0x5 0000	2	0x7 FADD		
3	0x6 0002				

	Process 1	Process 2			
Page Table base register	0x0010 0000	0x0050 0000			
Page Table Len register	0x0000 0004	0x0000 0003			
Virtual addr	0x0000 2004	0x0000 2004			
Physical addr =		?	?		
Virtual addr	0x0000 31A4	0x0000 31A4			
Physical addr =		?	?		

## **Page Table Entries**

- the primary payload of each page table entry (PTE) is a frame number
- PTEs typically contain other information as well, such as
  - information provided by the kernel to control address translation by the MMU, such as:
    - \* valid bit: is the process permitted to use this part of the address space?
    - \* present bit: is this page mapped into physical memory (useful with page replacement, to be discussed later)
    - \* protection bits: to be discussed
  - information provided by the MMU to help the kernel manage address spaces, such as:
    - \* reference (use) bit: has the process used this page recently?
    - \* dirty bit: has the process changed the contents of this page?

CS350 Operating Systems Fall 2015

Virtual Memory 14

#### Validity and Protection

- during address translation, the MMU checks that the page being used by the process has a *valid* page table entry
  - typically, each PTE contains a valid bit
  - invalid PTEs indicate pages that the process is not permitted to use
- the MMU may also enforce other protection rules, for example
  - each PTE may contain a *read-only* bit that indicates whether the corresponding page is read-only, or can be modified by the process
- if a process attempts to access an invalid page, or violates a protection rule, the MMU raises an exception, which is handled by the kernel

The kernel controls which pages are valid and which are protected by setting the contents of PTEs and/or MMU registers.

#### **Summary: Roles of the Kernel and the MMU**

- Kernel:
  - manage MMU state on address space switches (context switch from thread in one process to thread in a different process)
  - create and manage page tables
  - manage (allocate/deallocate) physical memory
  - handle exceptions raised by the MMU
- MMU (hardware):
  - translate virtual addresses to physical addresses
  - check for and raise exceptions when necessary

CS350 Operating Systems Fall 2015

Virtual Memory 16

#### **Speed of Address Translation**

- Execution of each machine instruction may involve one, two or more memory operations
  - one to fetch instruction
  - one or more for instruction operands
- Address translation through a page table adds one extra memory operation (for page table entry lookup) for each memory operation performed during instruction execution
  - Simple address translation through a page table can cut instruction execution rate in half.
  - More complex translation schemes (e.g., multi-level paging) are even more expensive.
- Solution: include a Translation Lookaside Buffer (TLB) in the MMU
  - TLB is a fast, fully associative address translation cache
  - TLB hit avoids page table lookup

#### **TLB**

- Each entry in the TLB contains a (page number, frame number) pair.
- If address translation can be accomplished using a TLB entry, access to the page table is avoided.
  - This is called a TLB hit.
- Otherwise, translate through the page table.
  - This is called a *TLB miss*.
- TLB lookup is much faster than a memory access. TLB is an associative memory - page numbers of all entries are checked simultaneously for a match. However, the TLB is typically small (typically hundreds, e.g. 128, or 256 entries).
- If the MMU cannot distinguish TLB entries from different address spaces, then
  the kernel must clear or invalidate the TLB on each address space switch.
  (Why?)

CS350 Operating Systems Fall 2015

Virtual Memory 18

#### **TLB Management**

- A TLB may be hardware-controlled or software-controlled
- In a hardware-controlled TLB, when there is a TLB miss:
  - The MMU (hardware) finds the frame number by performing a page table lookup, translates the virtual address, and adds the translation (page number, frame number pair) to the TLB.
  - If the TLB is full, the MMU evicts an entry to make room for the new one.
- In a software-controlled TLB, when there is a TLB miss:
  - the MMU simply causes an exception, which triggers the kernel exception handler to run
  - the kernel must determine the correct page-to-frame mapping and load the mapping into the TLB (evicting an entry if the TLB is full), before returning from the exception
  - after the exception handler runs, the MMU retries the instruction that caused the exception.

#### The MIPS R3000 TLB

- The MIPS has a software-controlled TLB that can hold 64 entries.
- Each TLB entry includes a virtual page number, a physical frame number, an address space identifier (not used by OS/161), and several flags (valid, read-only).
- OS/161 provides low-level functions for managing the TLB:

**TLB\_Write:** modify a specified TLB entry

**TLB\_Read:** read a specified TLB entry

TLB\_Probe: look for a page number in the TLB

• If the MMU cannot translate a virtual address using the TLB it raises an exception, which must be handled by OS/161.

See kern/arch/mips/include/tlb.h

CS350 Operating Systems Fall 2015

What is in a Virtual Address Space?

0x00400000 – 0x00401a0c
text (program code) and read—only data

growth

0x10000000 – 0x101200b0
data

0x000000000
0xffffffff

This diagram illustrates the layout of the virtual address space for the OS/161 test application user/testbin/sort

#### Address Translation In OS/161: dumbvm

- OS/161 starts with a very simple virtual memory implementation
- virtual address spaces are described by addrspace objects, which record the mappings from virtual to physical addresses

```
struct addrspace {
#if OPT_DUMBVM
  vaddr_t as_vbasel; /* base virtual address of code segment */
  paddr_t as_pbasel; /* base physical address of code segment *
  size_t as_npages1; /* size (in pages) of code segment */
  vaddr_t as_vbase2; /* base virtual address of data segment */
  paddr_t as_pbase2; /* base physical address of data segment *
  size_t as_npages2; /* size (in pages) of data segment */
  paddr_t as_stackpbase; /* base physical address of stack */
#else
  /* Put stuff here for your VM system */
#endif
};
```

• Notice that each segment must be mapped contiguously into physical memory.

CS350 Operating Systems Fall 2015

Virtual Memory 22

#### Address Translation Under dumbvm

- the MIPS MMU tries to translate each virtual address using the entries in the TLB
- If there is no valid entry for the page the MMU is trying to translate, the MMU generates a TLB fault (called an *address exception*)
- The vm\_fault function (see kern/arch/mips/vm/dumbvm.c) handles this exception for the OS/161 kernel. It uses information from the current process' addrspace to construct and load a TLB entry for the page.
- On return from exception, the MIPS retries the instruction that caused the exception. This time, it may succeed.

vm\_fault is not very sophisticated. If the TLB fills up, OS/161 will crash!

## Address Translation: OS/161 dumbvm Example

• Note: in OS/161 the stack is 12 pages and the page size is 4 KB = 0 x 1000.

Variable/Field	Process	: 1	Process 2			
as_vbase1	0x0040 00	000	0x0040	0000		
as_pbase1	0x0020 00	000	0x0050	0000		
as_npages1	0x0000 00	800	0x0000	0002		
as_vbase2	0x1000 00	000	0x1000	0000		
as_pbase2	0x0080 00	000	0x00A0	0000		
as_npages2	0x0000 00	10	0x0000	8000		
as_stackpbase	0x0010 00	000	0x00B0	0000		

	Process 1	Process 2				
Virtual addr	0x0040 0004		$0 \times 0040$	0004		
Physical addr =		?		?		
Virtual addr	0x1000 91A4		0x1000	91A4		
Physical addr =		?		?		
Virtual addr	0x7FFF 41A4		0x7FFF	41A4		
Physical addr =		?		?		
Virtual addr	0x7FFF 32B0		0x2000	41BC		
Physical addr =		?		?		

CS350 Operating Systems Fall 2015

Virtual Memory 24

# **Initializing an Address Space**

 When the kernel creates a process to run a particular program, it must create an address space for the process, and load the program's code and data into that address space

OS/161 *pre-loads* the address space before the program runs. Many other OS load pages *on demand*. (Why?)

- A program's code and data is described in an *executable file*, which is created when the program is compiled and linked
- OS/161 (and some other operating systems) expect executable files to be in ELF (Executable and Linking Format) format
- The OS/161 execv system call re-initializes the address space of a process int execv(const char \*program, char \*\*args)
- The program parameter of the execv system call should be the name of the ELF executable file for the program that is to be loaded into the address space.

#### **ELF Files**

- ELF files contain address space segment descriptions, which are useful to the kernel when it is loading a new address space
- the ELF file identifies the (virtual) address of the program's first instruction
- the ELF file also contains lots of other information (e.g., section descriptors, symbol tables) that is useful to compilers, linkers, debuggers, loaders and other tools used to build programs

CS350 Operating Systems Fall 2015

Virtual Memory 26

#### **Address Space Segments in ELF Files**

- The ELF file contains a header describing the segments and segment *images*.
- Each ELF segment describes a contiguous region of the virtual address space.
- The header includes an entry for each segment which describes:
  - the virtual address of the start of the segment
  - the length of the segment in the virtual address space
  - the location of the start of the segment image in the ELF file (if present)
  - the length of the segment image in the ELF file (if present)
- the image is an exact copy of the binary data that should be loaded into the specified portion of the virtual address space
- the image may be smaller than the address space segment, in which case the rest
  of the address space segment is expected to be zero-filled

To initialize an address space, the OS/161 kernel copies segment images from the ELF file to the specifed portions of the virtual address space.

#### ELF Files and OS/161

- OS/161's dumbvm implementation assumes that an ELF file contains two segments:
  - a text segment, containing the program code and any read-only data
  - a data segment, containing any other global program data
- the ELF file does not describe the stack (why not?)
- dumbvm creates a *stack segment* for each process. It is 12 pages long, ending at virtual address 0x7fffffff

Look at kern/syscall/loadelf.c to see how OS/161 loads segments from ELF files

CS350 Operating Systems Fall 2015

Virtual Memory 28

#### **ELF Sections and Segments**

• In the ELF file, a program's code and data are grouped together into *sections*, based on their properties. Some sections:

.text: program code

.rodata: read-only global data

.data: initialized global data

.bss: uninitialized global data (Block Started by Symbol)

.sbss: small uninitialized global data

- not all of these sections are present in every ELF file
- normally
  - the .text and .rodata sections together form the text segment
  - the .data, .bss and .sbss sections together form the data segement
- space for *local* program variables is allocated on the stack when the program runs

## The user/uw-testbin/segments.c Example Program (1 of 2)

```
#include <unistd.h>
#define N
             (200)
int x = 0xdeadbeef;
int t1;
int t2;
int t3;
int array[4096];
char const *str = "Hello World\n";
const int z = 0xabcddcba;
struct example {
  int ypos;
  int xpos;
};
CS350
                          Operating Systems
                                                          Fall 2015
```

Virtual Memory 30

## The user/uw-testbin/segments.c Example Program (2 of 2)

```
int
main()
{
  int count = 0;
  const int value = 1;
  t1 = N;
  t2 = 2;
  count = x + t1;
  t2 = z + t2 + value;

reboot(RB_POWEROFF);
  return 0; /* avoid compiler warnings */
}
```

#### **ELF Sections for the Example Program**

#### Section Headers:

```
[Nr] Name
                                  Addr
                                           Off
                                                  Size
                  Type
                                                         Flg
[ 0 ]
                  NULL
                                  0000000 000000 000000
                                  00400000 010000 000200
[ 1] .text
                                                          AX
                 PROGBITS

```

The cs350-objdump program can be used to inspect OS/161 MIPS ELF file section contents: cs350-objdump -s segments

CS350 Operating Systems Fall 2015

Virtual Memory 34

#### Contents of the Example Program's .rodata Section

The .rodata section contains the "Hello World" string literal and the constant integer variable z.

#### Contents of the Example Program's .data Section

The .data section contains the initialized global variables str and x.

CS350 Operating Systems Fall 2015

Virtual Memory 36

#### Contents of the Example Program's .bss and .sbss Sections

The t1, t2, and t3 variables are in the .sbss section. The array variable is in the .bss section. There are no values for these variables in the ELF file, as they are uninitialized. The cs350-nm program can be used to inspect symbols defined in ELF files: cs350-nm -n <filename>, in this case cs350-nm -n segments.

## An Address Space for the Kernel

- Each process has its own address space. What about the kernel?
- Three possibilities:

**Kernel in physical space:** disable address translation in privileged system execution mode, enable it in unprivileged mode

**Kernel in separate virtual address space:** need a way to change address translation (e.g., switch page tables) when moving between privileged and unprivileged code

# Kernel mapped into portion of address space of every process: OS/161,

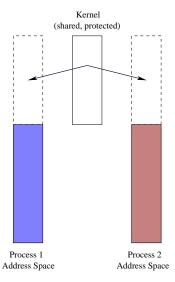

Linux, and other operating systems use this approach

- memory protection mechanism is used to isolate the kernel from applications
- one advantage of this approach: application virtual addresses (e.g., system call parameters) are easy for the kernel to use

CS350 Operating Systems Fall 2015

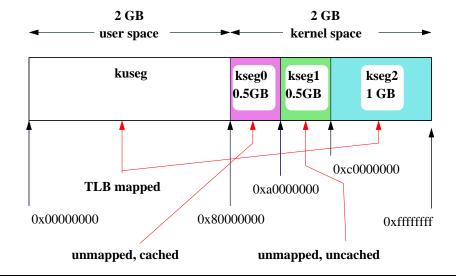

Virtual Memory 38

#### The Kernel in Process' Address Spaces

Attempts to access kernel code/data in user mode result in memory protection exceptions, not invalid address exceptions.

#### Address Translation on the MIPS R3000

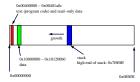

In OS/161, user programs live in kuseg, kernel code and data structures live in kseg0, devices are accessed through kseg1, and kseg2 is not used.

CS350 Operating Systems Fall 2015

Virtual Memory 40

#### The Problem of Sparse Address Spaces

- Consider the page table for user/testbin/sort, assuming a 4 Kbyte page:
  - need  $2^{19}$  page table entries (PTEs) to cover the bottom half of the virtual address space (2GB).
  - the text segment occupies 2 pages, the data segment occupies 289 pages, and OS/161 sets the initial stack size to 12 pages, so there are only 303 valid pages (of 2<sup>19</sup>).
- If dynamic relocation is used, the kernel will need to map a 2GB address space contiguously into physical memory, even though only a tiny fraction of that address space is actually used by the program.
- If paging is used, the kernel will need to create a page table with 2<sup>19</sup> PTEs, almost all of which are marked as not valid.

## **Handling Sparse Address Spaces**

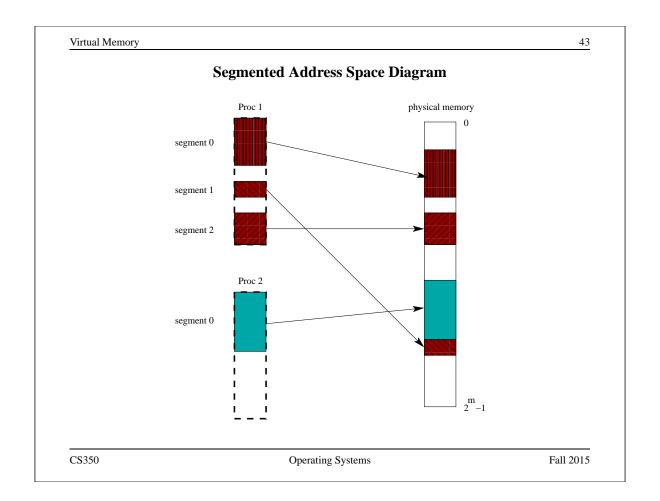

- Use dynamic relocation, but provide separate base and length for each valid segment of the address space. Do not map the rest of the address space.
  - OS/161 dumbvm uses a simple variant of this idea, which depends on having a software-managed TLB.
  - A more general approach is *segmentation*.
- A second approach is to use *multi-level paging* 
  - replace the single large linear page table with a hierarchy of smaller page tables
  - a sparse address space can be mapped by a sparse tree hierarchy
  - easier to manage several smaller page tables than one large one (remember:
     each page table must be continguous in physical memory!)

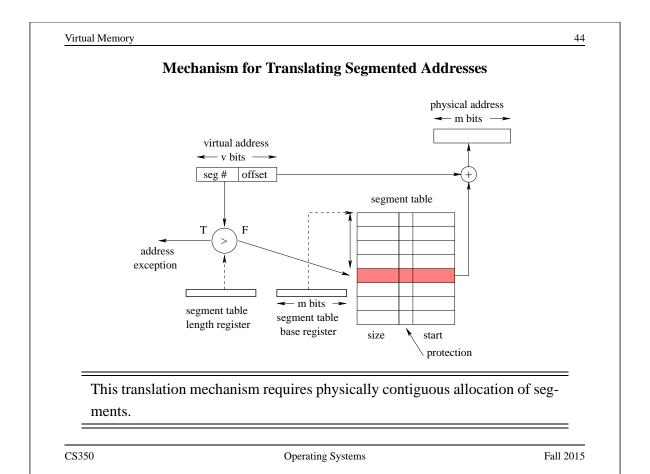

CS350 Operating Systems Fall 2015

Virtual Memory 42

#### Segmentation

- Often, programs (like sort) need several virtual address segments, e.g, for code, data, and stack.
- With segmentation, a virtual address can be thought of as having two parts: (segment ID, address within segment)
- Each segment also has a length.

## **Address Translation: Segmented Addresses Example**

• Virtual addr = 32 bits, physical addr = 32 bits, offset = 28 bits

Segment Table 1 @ 0x0010 0000					Segment Table 2 @ 0x0050 0000				
Seg	Size	Prot	Start	Seg	Size	Prot	Start		
0	0x6000	X-	0x7 0000	0	0x9000	X-	0x90 0000		
1	0x1000	-W	0x6 0000	1	0xD000	-W	0xAF 0000		
2	0xC000	-W	0x5 0000	2	0xA000	-W	0x70 0000		
3	0xB000	-W	0x8 0000						

	Process 1		Proces	s 2	
Seg Table base reg	0x0010 0000		0x0050	0000	
Seg Table Len	0x0000 0004		0x0000	0003	
Virtual addr	0x0000 2004		0x1000	В481

Virtual Memory 46

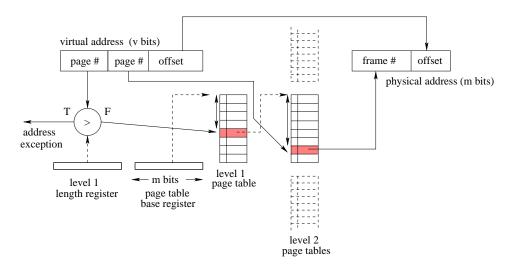

# **Handling Sparse Paged Virtual Address Spaces**

- Large paged virtual address spaces require large page tables.
- $\bullet$  example:  $2^{48}$  byte virtual address space, 8 Kbyte ( $2^{13}$  byte) pages, 4 byte page table entries means

$$\frac{2^{48}}{2^{13}}2^2 = 2^{37}$$
 bytes per page table

- page tables for large address spaces may be very large, and
  - they must be in memory, and
  - they must be physically contiguous

# **Two-Level Paging**

CS350 Operating Systems Fall 2015

Virtual Memory 52

# **Exploiting Secondary Storage**

#### **Goals:**

- Allow virtual address spaces that are larger than the physical address space.
- Allow greater multiprogramming levels by using less of the available (primary) memory for each process.

## Method:

- Allow pages (or segments) from the virtual address space to be stored in secondary storage, e.g., on disks, as well as primary memory.
- Move pages (or segments) between secondary storage and primary memory so that they are in primary memory when they are needed.

## **Paging Policies**

## When to Page?:

*Demand paging* brings pages into memory when they are used. Alternatively, the OS can attempt to guess which pages will be used, and *prefetch* them.

## What to Replace?:

Unless there are unused frames, one page must be replaced for each page that is loaded into memory. A *replacement policy* specifies how to determine which page to replace.

Similar issues arise if (pure) segmentation is used, only the unit of data transfer is segments rather than pages. Since segments may vary in size, segmentation also requires a *placement policy*, which specifies where, in memory, a newly-fetched segment should be placed.

CS350 Operating Systems Fall 2015

Virtual Memory 54

#### **Page Faults**

- When paging is used, some valid pages may be loaded into memory, and some may not be.
- To account for this, each PTE may contain a *present* bit, to indicate whether the page is or is not loaded into memory
  - -V=1, P=1: page is valid and in memory (no exception occurs)
  - -V=1, P=0: page is valid, but is not in memory (exception!)
  - -V = 0, P = x: invalid page (exception!)
- If V = 1 and P = 0, the MMU will generate an exception if a process tries to access the page. This is called a *page fault*.
- To handle a page fault, the kernel must:
  - issue a request to the disk to copy the missing page into memory,
  - block the faulting process
  - once the copy has completed, set P = 1 in the PTE and unblock the process
- the processor will then retry the instrution that caused the page fault

## Page Faults in OS/161

- things are a bit different in systems with software-managed TLBs, such as OS/161 on the MIPS processor
- MMUs with software-managed TLBs never check page tables, and thus do not interpret P bits in page table entries
- In an MMU with a software-managed TLB, either there is a valid translation for a page in the TLB, or there is not.
  - If there is not, the MMU generates an exception. It is up to the kernel to determine the reason for the exception. Is this:
    - \* an access to a valid page that is not in memory (a page fault)?
    - \* an access to a valid page that is in memory?
    - \* an access to an invalid page?
  - The kernel should ensure that a page has a translation in the TLB *only* if the page is valid and in memory. (Why?)

CS350 Operating Systems Fall 2015

Virtual Memory 56

#### A Simple Replacement Policy: FIFO

- the FIFO policy: replace the page that has been in memory the longest
- a three-frame example:

Num	1	2	3	4	5	6	7	8	9	10	11	12
Refs	a	b	c	d	a	b	e	a	b	c	d	e
Frame 1	a	a	a	d	d	d	e	e	e	e	e	e
Frame 2		b	b	b	a	a	a	a	a	c	c	c
Frame 3			c	c	c	b	b	b	b	b	d	d
Fault ?	X	Х	X	X	X	X	X			X	X	

# **Optimal Page Replacement**

• There is an optimal page replacement policy for demand paging.

• The OPT policy: replace the page that will not be referenced for the longest time.

Num	1	2	3	4	5	6	7	8	9	10	11	12
Refs	a	b	c	d	a	b	e	a	b	c	d	e
Frame 1	a	a	a	a	a	a	a	a	a	c	c	c
Frame 2		b	b	b	b	b	b	b	b	b	d	d
Frame 3			c	d	d	d	e	e	e	e	e	e
Fault ?	Х	Х	X	X			X			X	X	

• OPT requires knowledge of the future.

CS350 Operating Systems Fall 2015

Virtual Memory 58

## **Other Replacement Policies**

• FIFO is simple, but it does not consider:

**Frequency of Use:** how often a page has been used?

**Recency of Use:** when was a page last used?

**Cleanliness:** has the page been changed while it is in memory?

- The *principle of locality* suggests that usage ought to be considered in a replacement decision.
- Cleanliness may be worth considering for performance reasons.

## Locality

- Locality is a property of the page reference string. In other words, it is a property of programs themselves.
- *Temporal locality* says that pages that have been used recently are likely to be used again.
- *Spatial locality* says that pages "close" to those that have been used are likely to be used next.

In practice, page reference strings exhibit strong locality. Why?

CS350 Operating Systems Fall 2015

Virtual Memory 60

#### Least Recently Used (LRU) Page Replacement

- LRU is based on the principle of temporal locality: replace the page that has not been used for the longest time
- To implement LRU, it is necessary to track each page's recency of use. For example: maintain a list of in-memory pages, and move a page to the front of the list when it is used.
- Although LRU and variants have many applications, true LRU is difficult to implement in virtual memory systems. (Why?)

# **Least Recently Used: LRU**

• the same three-frame example:

Num	1	2	3	4	5	6	7	8	9	10	11	12
Refs	a	b	c	d	a	b	e	a	b	c	d	e
Frame 1	a	a	a	d	d	d	e	e	e	c	c	c
Frame 2		b	b	b	a	a	a	a	a	a	d	d
Frame 3			c	c	c	b	b	b	b	b	b	e
Fault ?	X	X	X	X	X	X	X			X	X	X

CS350 Operating Systems Fall 2015

Virtual Memory 62

## The "Use" Bit

- A use bit (or reference bit) is a bit found in each page table entry that:
  - is set by the MMU each time the page is used, i.e., each time the MMU translates a virtual address on that page
  - can be read and cleared by the operating system
- The use bit provides a small amount of efficiently-maintainable usage information that can be exploited by a page replacement algorithm.

## The Clock Replacement Algorithm

- The clock algorithm (also known as "second chance") is one of the simplest algorithms that exploits the use bit.
- Clock is identical to FIFO, except that a page is "skipped" if its use bit is set.
- The clock algorithm can be visualized as a victim pointer that cycles through the page frames. The pointer moves whenever a replacement is necessary:

```
while use bit of victim is set
   clear use bit of victim
  victim = (victim + 1) % num_frames
choose victim for replacement
victim = (victim + 1) % num_frames
```

CS350 Operating Systems Fall 2015

Virtual Memory 64

#### Page Cleanliness: the "Modified" Bit

- A page is *modified* (sometimes called dirty) if it has been changed since it was loaded into memory.
- A modified page is more costly to replace than a clean page. (Why?)
- The MMU identifies modified pages by setting a *modified bit* in page table entry of a page when a process *writes* to a virtual address on that page, i.e., when the page is changed.
- The operating system can clear the modified bit when it cleans the page
- The modified bit potentially has two roles:
  - Indicates which pages need to be cleaned.
  - Can be used to influence the replacement policy.

## **How Much Physical Memory Does a Process Need?**

- Principle of locality suggests that some portions of the process's virtual address space are more likely to be referenced than others.
- A refinement of this principle is the *working set model* of process reference behaviour.
- According to the working set model, at any given time some portion of a
  program's address space will be heavily used and the remainder will not be.
  The heavily used portion of the address space is called the *working set* of the
  process.
- The working set of a process may change over time.
- The resident set of a process is the set of pages that are located in memory.

According to the working set model, if a process's resident set includes its working set, it will rarely page fault.

CS350 Operating Systems Fall 2015

Virtual Memory 66

#### **Resident Set Sizes (Example)**

```
RSS COMMAND
PID
      VSZ
805 13940 5956 /usr/bin/gnome-session
831
           848 /usr/bin/ssh-agent
     2620
834
     7936 5832 /usr/lib/gconf2/gconfd-2 11
838
     6964 2292 gnome-smproxy
840 14720 5008 gnome-settings-daemon
848
   8412 3888 sawfish
851 34980 7544 nautilus
853 19804 14208 gnome-panel
857
     9656 2672 gpilotd
867
     4608 1252 gnome-name-service
```

## **Thrashing and Load Control**

- What is a good multiprogramming level?
  - If too low: resources are idle
  - If too high: too few resources per process
- A system that is spending too much time paging is said to be *thrashing*.
   Thrashing occurs when there are too many processes competing for the available memory.
- Thrashing can be cured by load shedding, e.g.,
  - Killing processes (not nice)
  - Suspending and swapping out processes (nicer)

CS350 Operating Systems Fall 2015

Virtual Memory 68

#### **Swapping Out Processes**

- Swapping a process out means removing all of its pages from memory, or marking them so that they will be removed by the normal page replacement process. Suspending a process ensures that it is not runnable while it is swapped out.
- Which process(es) to suspend?
  - low priority processes
  - blocked processes
  - large processes (lots of space freed) or small processes (easier to reload)
- There must also be a policy for making suspended processes ready when system load has decreased.
