#### What is a Process?

**Answer 1:** a process is an abstraction of a program in execution

**Answer 2:** a process consists of

- an address space, which represents the memory that holds the program's code and data
- a thread of execution (possibly several threads)
- other resources associated with the running program. For example:
- open files
- sockets
- attributes, such as a name (process identifier)

:

more than one thread is a concurrent process. A process with one thread is a sequential process. A process with

### Multiprogramming

Processes and the Kernel

- multiprogramming means having multiple processes existing at the same time
- most modern, general purpose operating systems support multiprogramming
- coordinated by the operating system: all processes share the available hardware resources, with the sharing
- Each process uses some of the available memory to hold its address space The OS decides which memory and how much memory each process gets
- OS can coordinate shared access to devices (keyboards, disks), since processes use these devices indirectly, by making system calls.
- the operating system. Processes timeshare the processor(s). Again, timesharing is controlled by
- OS ensures that processes are isolated from one another. Interprocess communication should be possible, but only at the explicit request of the processes involved.

#### The OS Kernel

- The kernel is a program. It has code and data like any other program.
- programs do not Usually kernel code runs in a privileged execution mode, while other

## **Kernel Privilege, Kernel Protection**

- What does it mean to run in privileged mode?
- Kernel uses privilege to
- control hardware
- protect and isolate itself from processes
- privileges vary from platform to platform, but may include:
- ability to execute special instructions (like halt)
- ability to manipulate processor state (like execution mode)
- ability to access memory addresses that can't be accessed otherwise
- change kernel code, or read or write kernel data, except through controlled kernel ensures that it is isolated from processes. No process can execute or mechanisms like system calls.

CS350 Operating Systems Spring 2011

Processes and the Kernel

#### System Calls

- System calls are an interface between processes and the kernel.
- A process uses system calls to request operating system services.
- From point of view of the process, these services are used to manipulate the abstractions that are part of its execution environment. For example, a process might use a system call to
- open a file
- send a message over a pipe
- create another process
- increase the size of its address space

### How System Calls Work

- a system call. Often, it is a special instruction, e.g., the MIPS syscall The hardware provides a mechanism that a running program can use to cause
- What happens on a system call:
- the processor is switched to system (privileged) execution mode
- key parts of the current thread context, such as the program counter, are
- the program counter is set to a fixed (determined by the hardware) memory address, which is within the kernel's address space

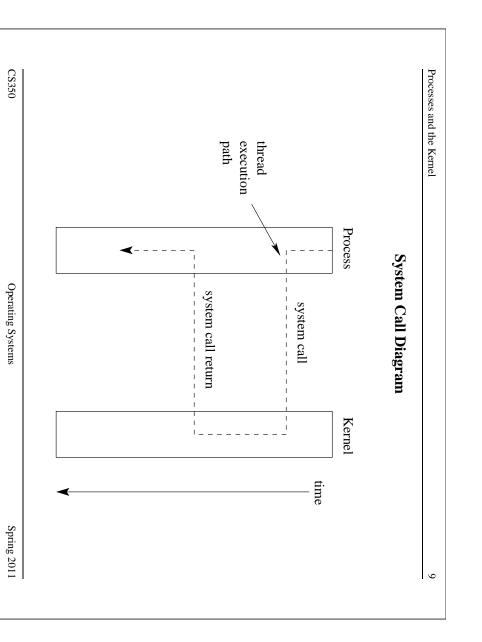

CS350 Operating Systems Spring 2011

Processes and the Kernel

### **System Call Execution and Return**

- Once a system call occurs, the calling thread will be executing a system call handler, which is part of the kernel, in system mode.
- The kernel's handler determines which service the calling process wanted, and performs that service.
- When the kernel is finished, it returns from the system call. This means:
- restore the key parts of the thread context that were saved when the system call was made
- switch the processor back to unprivileged (user) execution mode
- Now the thread is executing the calling process' program again, picking up where it left off when it made the system call.

in unprivileged mode. call return switches the thread back to executing application code and to start executing kernel code in privileged mode. The system A system call causes a thread to stop executing application code

Operating Systems

# **OS/161 close System Call Description**

#### Synopsis:

Library: standard C library (libc)

```
close(int fd);
              int
                          #include
                           <unistd.h>
```

**Description:** The file handle fd is closed. . . .

Return Values: On success, close returns 0. On error, -1 is returned and errno is set according to the error encountered.

#### Errors:

**EBADF:** fd is not a valid file handle

**EIO:** A hard I/O error occurred

OS/161 MIPS System Call Conventions

14

Processes and the Kernel

- When the syscall instruction occurs:
- An integer system call code should be located in register R2 (v0)
- Any system call arguments should be located in registers R4 (a0), R5 (a1), R6 (a2), and R7 (a3), much like procedure call arguments.
- When the system call returns
- register R7 (a3) will contain a 0 if the system call succeeded, or a 1 if the system call failed
- register R2 (v0) will contain the system call return value if the system call succeeded, or an error number (errno) if the system call failed

## **OS/161 System Call Code Definitions**

## **OS/161 User and Kernel Thread Stacks**

is used while the thread is executing privileged kernel code. thread is executing unprivileged application code, and another that Each OS/161 thread has two stacks, one that is used while the

19

# OS/161 MIPS Exception Handler (cont'd)

The common\_exception code does the following:

- allocates a trap frame on the thread's kernel stack and saves the user-level application's complete processor state (all registers except k0 and k1) into the trap frame.
- 2 calls the mips\_trap function to continue processing the exception.
- $\omega$ when mips\_trap returns, restores the application processor state from the trap frame to the registers
- 4. issues MIPS jr and rfe (restore from exception) instructions to return control to the application code. The jr instruction takes control back to processor to unprivileged mode occurred, and the rfe (which happens in the delay slot of the jr) restores the location specified by the application program counter when the syscall

Processes and the Kernel **CPU** registers stack application data code OS/161 Trap Frame trap frame with saved application state memory stack kernel data thread library code 20

state is saved in a trap frame on the thread's kernel stack, and the CPU registers are available to hold kernel execution state. While the kernel handles the system call, the application's CPU

21

# mips\_trap: Handling System Calls, Exceptions, and Interrupts

- On the MIPS, the same exception handler is invoked to handle system calls, exceptions and interrupts
- The hardware sets a code to indicate the reason (system call, exception, or interrupt) that the exception handler has been invoked
- mips\_trap function tests the reason code and calls the appropriate function: OS/161 has a handler function corresponding to each of these reasons. The the system call handler (mips\_syscall) in the case of a system call.
- mips\_trap can be found in kern/arch/mips/mips/trap.c.

Interrupts and exceptions will be presented shortly

Processes and the Kernel 24

#### **Exceptions**

- Exceptions are another way that control is transferred from a process to the
- a process. For example, arithmetic overflows, illegal instructions, or page Exceptions are conditions that occur during the execution of an instruction by faults (to be discussed later).
- exceptions are detected by the hardware
- when an exception is detected, the hardware transfers control to a specific
- normally, a kernel exception handler is located at that address

handling. (What is different?) Exception handling is similar to, but not identical to, system call

Processes and the Kernel 26

### **Interrupts** (Revisited)

- Interrupts are a third mechanism by which control may be transferred to the
- Interrupts are similar to exceptions. However, they are caused by hardware devices, not by the execution of a program. For example:
- a network interface may generate an interrupt when a network packet a disk controller may generate an interrupt to indicate that it has finished arrives
- a timer may generate an interrupt to indicate that time has passed writing data to the disk
- is saved, and control is transferred to a kernel interrupt handler at a fixed Interrupt handling is similar to exception handling - current execution context address

# Interrupts, Exceptions, and System Calls: Summary

- interrupts, exceptions and system calls are three mechanisms by which control is transferred from an application program to the kernel
- when these events occur, the hardware switches the CPU into privileged mode and transfers control to a predefined location, at which a kernel handler should be located
- the handler saves the application thread context so that the kernel code can be executed on the CPU, and restores the application thread context just before control is returned to the application

CS350 Operating Systems Spring 2011

Processes and the Kernel 28

### **Implementation of Processes**

- The kernel maintains information about all of the processes in the system in a data structure often called the process table.
- Per-process information may include:
- process identifier and owner
- current process state and other scheduling information
- lists of resources allocated to the process, such as open files
- accounting information

each OS/161 process has a single thread. pointer) is kept in the thread structure. This works only because In OS/161, some process information (e.g., an address space

29

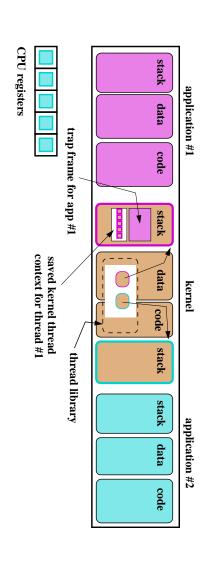

### Implementing Timesharing

- whenever a system call, exception, or interrupt occurs, control is transferred from the running program to the kernel
- running process' thread to another process' thread at these points, the kernel has the ability to cause a context switch from the
- notice that these context switches always occur while a process' thread is executing kernel code

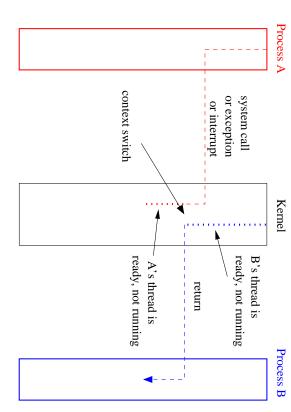

thread, the kernel timeshares the processor among multiple processes. By switching from one process's thread to another process's

Processes and the Kernel **Two Processes in OS/161** 30

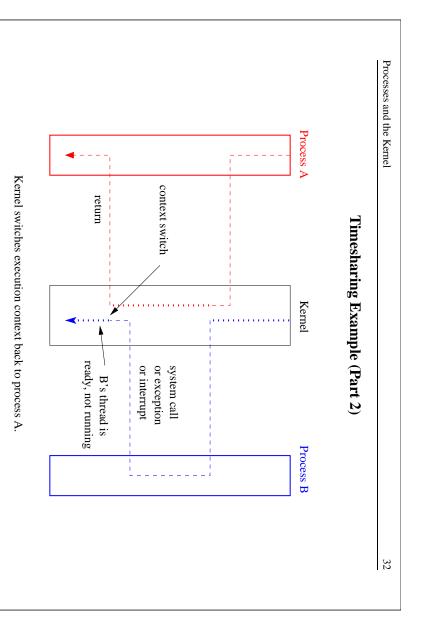

Kernel switches execution context to Process B.

Operating Systems

Spring 2011

CS350

CS350

Operating Systems

Spring 2011

### Implementing Preemption

- the kernel uses interrupts from the system timer to measure the passage of time and to determine whether the running process's quantum has expired.
- a timer interrupt (like any other interrupt) transfers control from the running program to the kernel.
- this gives the kernel the opportunity to preempt the running thread and dispatch a new one.

### The Process Model

36

Processes and the Kernel

straightforward, there are some less obvious aspects of process behaviour that Although the general operations supported by the process interface are must be defined by an operating system.

**Process Initialization:** When a new process is created, how is it initialized? have any other resources? What is in the address space? What is the initial thread context? Does it

Multithreading: Are concurrent processes supported, or is each process limited to a single thread?

Inter-Process Relationships: Are there relationships among processes, e.g., parent/child? If so, what do these relationships mean?
