What is an Operating System?

- Three views of an operating system

  Application View: what services does it provide?

  System View: what problems does it solve?

  Implementation View: how is it built?

  An operating system is part cop, part facilitator.

Application View of an Operating System

- The OS provides an execution environment for running programs.

  – The execution environment provides a program with the processor time and memory space that it needs to run.

  – The execution environment provides interfaces through which a program can use networks, storage, I/O devices, and other system hardware components.

    * Interfaces provide a simplified, abstract view of hardware to application programs.

  – The execution environment isolates running programs from one another and prevents undesirable interactions among them.

Other Views of an Operating System

System View: The OS manages the hardware resources of a computer system.

- Resources include processors, memory, disks and other storage devices, network interfaces, I/O devices such as keyboards, mice and monitors, and so on.

- The operating system allocates resources among running programs. It controls the sharing of resources among programs.

- The OS itself also uses resources, which it must share with application programs.

Implementation View: The OS is a concurrent, real-time program.

- Concurrency arises naturally in an OS when it supports concurrent applications, and because it must interact directly with the hardware.

- Hardware interactions also impose timing constraints.

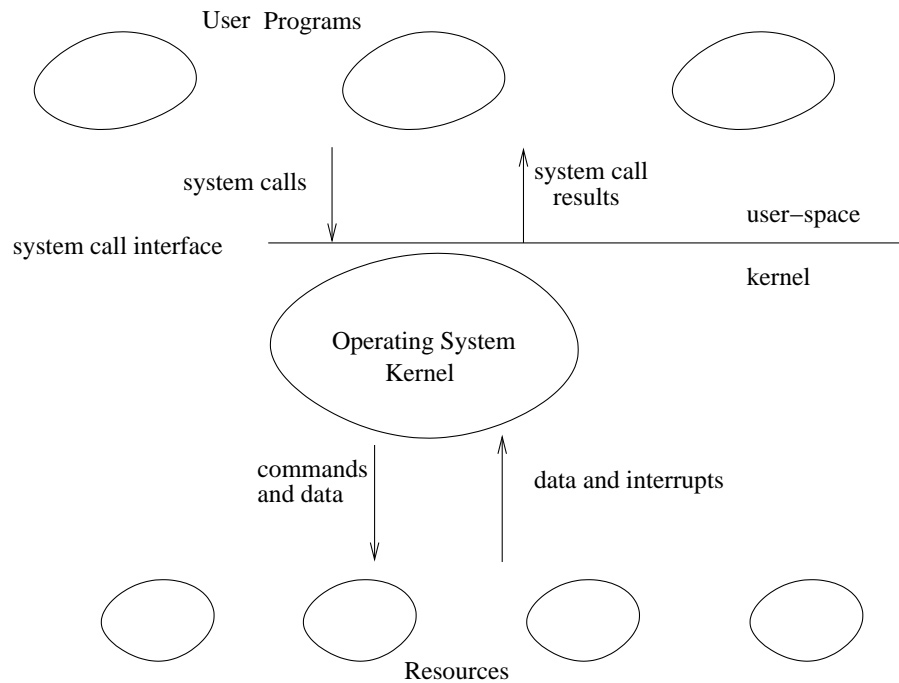

The Operating System and the Kernel

- Some terminology:

  kernel: The operating system kernel is the part of the operating system that responds to system calls, interrupts and exceptions.

  operating system: The operating system as a whole includes the kernel, and may include other related programs that provide services for applications. This may include things like:
  - utility programs
  - command interpreters
  - programming libraries

Operating System Abstractions

- The execution environment provided by the OS includes a variety of abstract
  entities that can be manipulated by a running program. Examples:

  files and file systems: abstract view of secondary storage

  address spaces: abstract view of primary memory

  processes, threads: abstract view of program execution

  sockets, pipes: abstract view of network or other message channels

- This course will cover
  - why these abstractions are designed the way they are
  - how these abstractions are manipulated by application programs
  - how these abstractions are implemented by the OS

Course Outline

- Introduction

- Threads and Concurrency

- Synchronization

- Processes and the Kernel

- Virtual Memory

- Scheduling

- Devices and Device Management

- File Systems

- Interprocess Communication and Networking (time permitting)
