1. Introduction

1.1 Purpose

The purpose of this document is to provide a consistent and complete description of the requirements for the software of an elevator controller. The requirements will be presented using textual descriptions to explain concepts, different types of diagrams to illustrate complicated interactions, and tables to relate relevant information.

The intended audience of this document is all of the stakeholders for a project involving the development of elevator controller software. This includes, but is not limited to, software developers, project managers, quality assurance personnel, and customers.

1.2 Scope

The software of the elevator controller is responsible for the safe and efficient operation of all of the other components within the elevator system. The controller’s main goal is essentially to handle input signals from other components and respond accordingly with output signals. Two of the main computational obligations of the controller are to have a queuing system to log and process requests from passengers and to navigate the cabs of the elevators between floors in response to those requests. One of the other important objectives of the controller is ensure the safety of the passengers using the elevator system at all times. This is achieved through the interaction with certain components dedicated to monitoring environment attributes that are important to safety.

The controller, however, is not responsible for adapting its behavior to a high volume of requests. It uses the same algorithm to respond to requests regardless of the current state of the environment.

It is important to note that this SRS document only pertains to the requirements of the software of the elevator controller. It does not include requirements for the hardware that it will be deployed on. It also does not include requirements for the other components of the elevator system. Other components are mentioned because the requirements of the controller are indeed based on the interactions between it and the other components of the system; however, the requirements of the other components, as well as the overall elevator system itself, is outside the scope of this document and is therefore not included.
1.3 Definitions, Acronyms, and Abbreviations

Definitions:

Sheave: A component with a groove around its circumference to support and contain a rope or cable and a bearing at its center to permit rotation about a shaft. [2]

Acronyms:

UC: Use Case

SRS: Software Requirements Specification

1.4 Terminology

Elevator doors / doors: Refers to the inner door on an elevator cab and the corresponding outer door on the elevator shaft at the same floor at which the elevator cab is currently stopped at.

Note: This definition is useful because the door opening device on an elevator cab always opens the outer door of the shaft at the same time as the inner door of the cab. There is virtually no need to refer to the inner and outer doors separately.

Position marker: A position marker is a something on the side of an elevator shaft that is typically detected by some kind of sensor on an elevator cab inside of the shaft. There are many position markers all lined up through out the height of the shaft. The sensor reports the detection of these markers to a computer so that it can determine the position of the elevator cab that the sensor is attached to. An example of a position marker is a hole.

Active Summon / Floor Request: An active summon or floor request is a summon or floor request that has not yet been fulfilled by the arrival of an elevator cab. A summon or floor request becomes active when the appropriate button is pressed. It becomes inactive when a cab arrives at the summoned from or requested floor.

1.6 Overview

The rest of this SRS document contains all of the requirements for the elevator controller presented in several ways and organized into different sections.

Section 2 contains general information that is not too specific and is provided as a background for the following sections. It contains descriptions of all of the other elevator components that the controller interacts with, as well as a context diagram that illustrates the entire elevator system. It also lists product functions, constraints, and assumptions about the controller. Section 2 is a good section for customers to read.

Section 3 contains more detail and presents the requirements with many different diagrams that illustrate the functional requirements of the elevator controller. Some of the types of diagrams that are used here include, sequence diagrams, state diagrams, and collaboration diagrams. There is also a part of this section that describes the interface between the controller and the rest of the elevator system as a set of signals. Section 3 is most suitable for developers and testers.

Section 4 of the SRS contains supplementary information required to complete the document’s breadth. It includes tables of all of the functional and non-functional requirements, as well as a table for each use case of the elevator controller. Both the requirements and the use cases are cross referenced with each other to provide traceability among both types of artifacts.

2. General Description

The product described in this document is software for an elevator controller. The controller is part of a larger elevator system comprised of several components other than the controller that are required to operate the elevator on a day-to-day basis. The elevator controller is responsible for directing the operation of most of the other components of
the system. If it functions correctly, the controller allows passengers to use the elevator system in an intuitive and efficient manner. Note that this particular system is comprised of two elevator shafts, each with their own cab. The elevators provide service to 6 floors.

## 2.1 Product Perspective

The elevator controller directly interacts with the following other components of the entire elevator system:

### Buttons

**Summon Buttons:** These buttons are on a button panel on the outside of the elevator shafts and are used by potential passengers to call an elevator cab to the floor that the pressed summon button is located on. There are two summon buttons on each floor – one for up, another for down, except on the top floor where there is only down and on the bottom floor where there is only up. The controller interacts with these buttons by receiving press and release signals indicating the requested direction and floor number. It also sends light on/off signals to indicate the status of the buttons.

**Floor Request Buttons:** This particular elevator controller will be controlling elevator cabs that are in a building with 6 floors. Consequently, each cab has 6 floor request buttons labeled 1 through 6 that passengers can use to direct the elevator cabs to the floor that they would like to go to. These buttons are located on a button panel on the interior of each elevator cab. The controller interacts with these buttons by receiving pressed signals indicating the desired floor number and elevator cab which they were pressed from. It also sends light on/off signals to indicate the status of the buttons.

**Open Door Button:** This button is on the interior button panel of each cab. A passenger can press this button to open the elevator doors or keep pressing it to keep them open, but only when the elevator cab is stopped at a floor. Some elevator systems also have a close door button, but this one does not. The controller interacts with this button by receiving a signal when it is pressed and when it is released. Both of these signals include the cab from which they came from.

**Emergency Stop Button:** This button is on the interior button panel of each cab. A passenger can press this button to stop the elevator no matter where it is in a shaft. The controller interacts with this button by
receiving a signal from it that indicates that it was pressed, as well as the cab that it came from.

**Emergency Bell Button:** This button is on the interior button panel of each cab. A passenger can press this button to sound a bell to alert people outside of the elevator shaft that someone is trapped inside the elevator cab in case of a malfunction. The controller interacts with this button by receiving a signal from it that indicates that it was pressed.

**Service Switch:** This feature of the elevator system is used to keep an elevator cab from moving and to keep the elevator doors from either opening or closing. It is useful for loading large items such as furniture into an elevator cab. The controller interacts with the switch by receiving a signal from it when it has been toggled to either AUTO or HOLD mode. AUTO is for normal operation; HOLD is to keep the elevator cab from moving and its doors from opening or closing.

**Displays**

**Floor Number Display:** The interior of each elevator cab has a display that indicates to its passengers which floor the elevator cab is currently on. Some elevator systems have this floor number display on every floor outside of the elevator doors, but this system does not. The controller interacts with this display by sending a signal that tells it which floor number to display.

**Direction Display:** The interior of each elevator cab has a display that indicates the current direction of an elevator cab; it is either up or down. The controller interacts with this display by sending it a signal that tells it which direction to display.

**Sensors**

**Load Sensor:** The floor of each elevator cab has a load sensor that keeps track of how much weight there is in the elevator cab at any given time. The controller interacts with the load sensor by receiving a signal from it whenever the total weight that is currently in the elevator cab has changed. The signal indicates the new load inside of the elevator cab and the cab from which the signal is coming from.
Position Marker Sensor: Each elevator cab has a position marker sensor that can detect position makers (defined in section 1.3) on the inside of the elevator shaft. The controller interacts with the floor sensor by receiving a signal from it whenever it detects a position marker. The signal also includes which elevator cab it is coming from.

Bells

Emergency Bell: Somewhere in the elevator system is an emergency bell that is used to alert people outside of the elevator system that someone is trapped inside an elevator cab. The controller interacts with the emergency bell by sending it a signal to ring.

Load Bell: Each cab has a load bell that is used to alert the passengers inside the cab that there is too much weight in it to operate it safely. The controller interacts with the load bell by sending it a signal to ring.

Mechanical

Door Opening Device: On top of each elevator cab is a door opening device. This device opens the inner door of the elevator cab and the outer door of the elevator shaft simultaneously at each floor. The controller interacts with the door opening device by sending signals to open or close the doors and by receiving signals when the doors have been completely opened or closed. The signals that the controller receives also indicate which cab they are coming from.

Elevator Engine: The elevator engine is responsible for moving an elevator cab up and down between floors. As this elevator system uses a roped mechanism, the elevator engine is connected to a sheave which the ropes are looped around. The controller interacts with the elevator engine by sending it a signal that specifies at which speed and in what direction the engine should be going in. A stop signal is simply constructed by setting the speed parameter of the signal to zero.
2.2 Product Functions

The primary function of the elevator controller is essentially to receive and process a variety of signals from several different components of a whole elevator system. It is able to send signals in response to the ones it receives in order to operate all of the other components in the system. This exchange of signals is how the elevator controller is able to keep the elevators running smoothly on a day-to-day basis.

Here are a few of the following ways the controller interacts with the other components of the elevator system:

- Controls the speed of elevator engines in order to move elevator cabs up and down their respective shafts.
- Queues and processes elevator summons and floor requests from passengers through the signals provided to it by several buttons.
• Processes information sent to it by load sensors in order to ensure that the load of a cab never exceeds the safety limit.
• Processes information sent to it by position marker sensors in order to keep track of where the elevator cabs are at all times, as well as their speed.
• Provides feedback to passengers through the lights on some of the buttons and the floor number and direction displays in each cab.
• Can sound alarm bells that are either invoked by trapped passengers or required to warn of excess load in a cab.
• Controls the operation of the elevator doors of a cab through communication with door opening devices.

2.3 User Characteristics

The users of the elevator controller are essentially the other components of the elevator system that interact with it (see section 2.1). The integral characteristic that these other components must have is being able to send and/or receive signals from the elevator controller. They must use the same protocol or format for signals as the controller does, so that communication between them is feasible. Also, some components, such as the elevator engines and door opening devices, must be able to process and react to the signals sent to it by the controller in a timely fashion. Otherwise, the elevator system may become too slow to be useful.

2.4 General Constraints

The hardware that the elevator controller software will be running on may constrain some design decisions pertaining to timing and performance, as well as signal communication.

Also, certain rules about public safety impose specific requirements on the elevator controller. The following is a list of constraints pertaining to the safety of the elevator system that the controller must manage:

• The inner doors of a cab should not be opened unless the cab is at a correct floor position and is stopped.
• The outer doors of a shaft should not be opened at a particular floor unless there is a cab stopped at that floor.
• An elevator cab should not start to move until its doors are completely closed.
• The acceleration and deceleration of a cab must be gradual enough to prevent the injury of any of the passengers inside.
• If the total weight in a cab has exceeded the safety limit, it should not resume normal operation until the total weight in the cab has been lowered below the safety limit.
• If the controller detects a malfunction in any of the other vital components of the elevator system, it must halt the operation of the affected cabs immediately.

2.5 Assumptions and Dependencies

The following is a list of assumptions made about the elevator system that affect the elevator controller:

• There are 6 floors that the elevator system provides service to.
• There are 2 elevator cabs that the controller is responsible for, each operating in its own, separate shaft.
• The performance of the elevator system must be reasonable; however, the controller does not have to perform special accommodations for high traffic periods during the day or unexpected burst increases in summon requests.
• The other components of the system that the controller must interact with can communicate with the controller by sending and receiving signals that conform to some agreed upon protocol or standard.
• There are a number of emergency functions throughout the elevator system. The elevator controller deals with these functions separately when they occur. There are no global emergency modes that the elevator controller goes into.
  o Emergency Bell Button Pressed
    ▪ This only causes the emergency bell of the system to ring, nothing more.
  o Emergency Stop button Pressed
    ▪ This causes the cab from which the button was pressed from to stop. The controller remains active and keeps accepting requests because the other cab may still be functional and a stopped cab can certainly start answering requests once its normal operation is resumed. Assume that a subsequent press of the emergency stop button after a cab has been stopped causes the cab to resume normal operation.
  o Load Sensor Detects Too Much Weight
    ▪ Likewise, this only affects the cab with too much weight inside, requests are still logged and queued normally by the controller – it does not enter any specific mode of emergency operation.
  o Service Switch
    ▪ Switching a cab into hold mode can be performed manually in the event of an emergency, but not necessarily. Regardless of the context, like the other events mentioned above, the controller still operates normally while taking into account the held cab – it does not enter any specific mode of emergency operation.
3. Specific Requirements

3.1 Functional Requirements

3.1.1 Overall System

3.1.1.1 System Sequence Diagrams

3.1.1.2 System State Diagrams

Figure 17: High Level System State Diagram

[State Diagram showing the states Off, Initializing, Shutting Down, Operating Elevator, and their transitions]
Figure 18 is an important state diagram. It implies that there is a lot of concurrency within the elevator controller. This concurrency is essential because of the fact that most input signals need to be handled as soon as they are received and input
signals can not be lost simply because the controller is in one specific state instead of another. After close examination, it is evident that all 6 sub-states shown in the Operating Elevator state must run within the controller concurrently.

Usually, when there is a lot of concurrency within a system or sub-system, data synchronization issues arise. However, the most important data stored in the controller is a queue, and its management is trivial. The two logging sub-states can only add requests to the queue, while the dispatching sub-state only processes and removes requests from it. Since the controller does not enter any specific emergency modes, the other 3 sub-states can operate concurrently without any concerns. For example, even though the emergency stop button is pressed from a cab that should not mean that requests should not be logged. Another cab can still answer requests while one cab is stopped and the stopped cab can resume answering requests from the queue when its normal operation is resumed.

**Figure 19: Dispatching Requests State Diagram**

![Dispatching Requests State Diagram](image-url)
To elaborate on the embedded note in Figure 19, the fork in the diagram is very important. It means that after the best cab to answer a request is determined, the current process branches into two new processes. One of the new processes is created to control the selected cab into answering the request. The other process goes back to the start state and checks the queue for more requests. This branch is necessary because of the fact that the elevator controller can operate two cabs simultaneously. While one cab is answering a request, the controller does not wait until that request has been answered to dispatch the next request; it does it as soon as the previous request has been delegated to a cab. Note that if both cabs are currently answering requests, the controller will stay in the state “Determining Best Cab to Answer Request” until one of them becomes free.

Figure 20: Controlling Cab State Diagram
There is a tricky situation in the state diagram of Figure 21. You can see that the Cab Suspended state can be entered from any of the three states in Operating Doors, not just Doors Opened. The reason for this is that a passenger could sneak into the elevator cab while the doors are opening or closing and cause the total weight of the cab to exceed the safety limit. So the cab can become suspended while the doors are opening or closing, not just when they are fully opened. The Cab Suspended state only returns to the Doors Opened state because the doors are opened when a cab becomes suspended and remain that way until normal operation resumes.
Figure 22: Logging Floor Requests State Diagram

Figure 23: Logging Summon Requests State Diagram
Handling Service Switch Mode Toggle State Diagram

This state machine generally handles both cases where a cab was stopped in HOLD mode and has to start again or was in AUTO mode and needs to be stopped and suspended.

- **Waiting for Signal from Service Switch**
- **ServiceSwitch.HoldMode(cabID)**
- **ServiceSwitch.AutoMode(cabID)**

- **Checking Current Service Mode of Cab**

- **Calculating New Speed Based on Service Mode Change**
  - Restrictions Determined [Cab in AUTO Mode]
  - New Speed Calculated [Cab at Appropriate Speed]

- **Determining Operation Restrictions Based on Current Service Mode**
  - Restrictions Determined [Cab in HOLD Mode]
  - Restrictions Determined [Cab not at Appropriate Speed]

- **PositionMarkerSensor.MarkerDetected(cabID)** [cabID == this cab]

- **Waiting for Marker Detected Signal from Position Marker Sensor**

Handling Service Switch Mode Toggle

- **Determining Operation Restrictions Based on Current Service Mode**
  - Restrictions Determined [Cab in AUTO Mode]
  - Restrictions Determined [Cab in HOLD Mode]

- **Calculating New Speed Based on Service Mode Change**
  - New Speed Calculated [Cab at Appropriate Speed]

- **PositionMarkerSensor.MarkerDetected(cabID)** [cabID == this cab]

- **Waiting for Marker Detected Signal from Position Marker Sensor**

- **Determining Operation Restrictions Based on Current Service Mode**
  - Restrictions Determined [Cab in AUTO Mode]
  - Restrictions Determined [Cab in HOLD Mode]
Figure 25: Handling Emergency Stop Button Presses State Diagram

This state machine generally handles both cases where a cab has already been stopped by the emergency stop button and needs to be started again or is not already stopped and needs to be halted.
3.1.1.3 System State Diagrams with Concepts
Since there are two cabs available, one cab can answer a request while the controller finds another request for the other cab. This is achieved by having a separate thread for the control of each cab, created by this fork.
Cab Controller

Controlling Cab

Cab Controller

Cab Stopped and Doors Closed

Request Retrieved, Loaded, and Analyzed

Cab Navigator

Calculating New Direction and Speed

New Direction and Speed Calculated
Engine.Move(speed, direction), DirectionDisplay.Show(direction)

Floor Request Logger  
Logging Floor Requests

Floor Request Logger
Waiting for Pressed Signal from Floor Request Button

Floor Request Queued
FloorRequestButton.Pressed( cabID, floorNumber )
[A cab is not stopped at requested floor] /
FloorRequestButton.TurnLightOn()

Floor Request Logger
Adding Floor Request to Queue

Summon Request Logger  
Logging Summon Requests

Summon Request Logger
Waiting for Pressed Signal from Summon Button

Summon Request Queued
SummonButton.Pressed( florrNumber, direction )
[A Cab is not stopped at summon floor] /
SummonButton.TurnLightOn()

Summon Request Logger
Adding Summon Request to Queue
Waiting for Signal from Service Switch

ServiceSwitch.AutoMode(cabID)

Checking Current Service Mode of Cab

ServiceSwitch.HoldMode(cabID)

Calculating New Speed Based on Service Mode Change

Restrictions Determined
(Cab in HOLD Mode) / Suspend Cab
Cab Controller

Restrictions Determined
(Cab in AUTO Mode) / Allow Normal Operation
Cab Controller

New Speed Calculated
(Cab at Appropriate Speed)

New Speed Calculated
(Cab not at Appropriate Speed) / Engine.Move(speed, direction)
Cab Navigator

Waiting for Marker Detected Signal from Position Marker Sensor

PositionMarkerSensor.MarkerDetected(cabID)
(cabID == this cab)

This state machine generally handles both cases where a cab was stopped in HOLD mode and has to start again or was in AUTO mode and needs to be stopped and suspended.
Emergency Stop Handler

Handling Emergency Stop Button Presses

- **Emergency Stop Handler**: Waiting for Pressed Signal from Emergency Stop Button

  - `EmergencyStopButtonPressed(cabID)`

  - State of Cab Determined

  - **Cab Controller**: Checking State of Cab

  - New Speed Calculated
    - [Cab at Appropriate Speed]

  - **Cab Navigator**: Calculating New Speed Based on Cab State

  - New Speed Calculated
    - [Cab not at Appropriate Speed]
    - [Engine.Move(speed, direction)]

  - **Cab Navigator**: Waiting for Marker Detected Signal from Position Marker Sensor

  - PositionMarkerSensor.MarkerDetected(cabID)

  - [cabID == this cab]

This state machine generally handles both cases where a cab has already been stopped by the emergency stop button and needs to be started again or is not already stopped and needs to be halted.
Waiting for Pressed Signal from Emergency Bell Button

EmergencyBellButton.Pressed() / EmergencyBell.Ring()

Handling Emergency Bell Button Presses

3.2 External Interface Requirements

3.2.1 User Interfaces

Since the elevator controller is an embedded software system, it does not have a visual interface that provides prompts or feedback to its users.

3.2.2 Hardware Interface-Application Program Interface

This SRS only pertains to the requirements of the software of an elevator controller, not the hardware that it runs on. Therefore, the details of hardware interface requirements are out of the scope of this document. That being said, the elevator controller hardware must provide a means of sending and receiving communication signals from other components of the elevator system in order for the software to be able to function properly. These signals are listed in the section below. They are simply invoked or handled by the controller software based on if the signal is input or output, with respect to the controller.

3.2.3 Communications Interface

Figure 51: Use Case Groupings

<<system>>
Elevator Controller

<<subsystem>>
Operation Control
- Process Pressed Signal from Summon Button
- Process Released Signal from Summon Button
- Process Pressed Signal from Open Door Button
- Process Released Signal from Open Door Button
- Process Pressed Signal from Floor Request Button
- Process RELEASED Signal from Service Switch

<<subsystem>>
Safety
- Process Pressed Signal from Emergency Stop Button
- Process Weight Signal from Load Sensor

<<subsystem>>
Maintenance
- Process Off Signal from Operator
- Process On Signal from Operator

<<subsystem>>
Navigation
- Process Detection Signal from Position Marker Sensor
- Process Doors Opened Signal from Door Opening Device
- Process Doors Closed Signal from Door Opening Device
4.4 Index

A
AUTO Mode............................................................................................................................................. 19, 71

C
Cab ........................................................................................................................................ 27, 28, 63, 64, 65, 66
Collaboration Diagram ......................................................................................................................... 41
Conceptual Diagram .............................................................................................................................. 42
Controller ............................................................................................................................................. 65, 67, 68, 69, 70, 71, 72, 73, 74

D
Direction Display ................................................................................................................................. 9, 63, 65, 74
Door Opening Device .......................................................................................................................... 23, 24, 62, 63, 67, 68, 69, 71, 72, 74, 75

E
Emergency Bell ..................................................................................................................................... 9, 10, 13, 18, 32, 62, 63, 64, 70, 71
Emergency Bell Button ......................................................................................................................... 13, 18, 32, 62, 64, 70, 71
Emergency Stop Button ....................................................................................................................... 18, 31, 62, 64, 65, 70
Engine .................................................................................................................................................. 10, 63, 67, 68, 70, 71, 72, 73, 74

F
Floor Number Display .......................................................................................................................... 63, 65, 72
Floor Request Button ........................................................................................................................... 16, 62, 63, 65, 68
Functional Requirement .......................................................................................................................... 14, 63

H
HOLD Mode........................................................................................................................................ 19, 71

I
Inner Door .......................................................................................................................................... 66
Input Signal ........................................................................................................................................ 62
Interface ............................................................................................................................................... 62

L
Load Bell ........................................................................................................................................... 10, 63, 65, 72
Load Sensor ......................................................................................................................................... 9, 13, 20, 62, 72

N
Non-Functional Requirement ................................................................................................................  66

O
Open Door Button ............................................................................................................................... 8, 17, 62, 64, 69, 70, 74
Outer Door .......................................................................................................................................... 66
Output Signal ........................................................................................................................................ 63

P
Position Marker Sensor ........................................................................................................................ 21, 62, 67, 68, 70, 71, 72

S
Sequence Diagram ............................................................................................................................... 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 51
Service Switch ..................................................................................................................................... 9, 13, 19, 30, 62, 64, 65, 71
Sheave ................................................................................................................................................ 6
State Diagram .................................................................24, 25, 26, 27, 28, 29, 30, 31, 32, 43
Summon Button ...............................................................8, 14, 15, 62, 63, 64, 65, 67, 68, 72, 73, 74
Use Case ..............................................................................6, 63, 67, 68, 69, 70, 71, 72, 73, 74, 76
